(54) Title: WOUND CLEANSING APPARATUS WITH FLOWSTRESS

Section View on X-X

(57) Abstract: An apparatus for cleansing wounds with means for applying flow stress to the wound bed, in which irrigant fluid from a reservoir connected to a conformable wound dressing and wound exudate from the dressing are recirculated by a device for moving fluid through a flow path which passes through the dressing and a means for fluid cleansing and back to the dressing. The cleansing means (which may be a single-phase, e.g. micro-filtration, system or a two-phase, e.g. dialytic system) removes materials deleterious to wound healing, and the cleansed fluid, still containing materials that are beneficial in promoting wound healing, is returned to the wound bed. The means for applying flow stress to the wound bed promotes wound healing. The dressing and a method of treatment using the apparatus.

WOUND CLEANSING APPARTUS WITH FLOWSTRESS

The present invention relates to apparatus and a medical wound dressing for irrigating, flow stressing and/or cleansing wounds, and a method of treating wounds using such apparatus for irrigating, flow stressing and/or cleansing wounds.

It relates in particular to such an apparatus, wound dressing and method that can be easily applied to a wide variety of, but in particular chronic, wounds, to cleanse them of materials that are deleterious to wound healing, whilst retaining materials that are beneficial in some therapeutic aspect, in particular to wound healing.

Before the present invention, aspirating and/or irrigating wounds and apparatus therefor were known, and tended to be used to remove wound exudate during wound therapy. In known forms of such wound therapy, the offtake from the wound, especially when in a highly exuding state, is voided to waste, e.g. to a collection bag.

20 Materials deleterious to wound healing are removed in this way.

5

10

15

25

30

35

However, materials that are beneficial in promoting wound healing, such as growth factors, naturally occurring anti-inflammatories, and other physiologically active components of the exudate from a wound are lost to the site where they can be potentially of most benefit, i.e. the wound bed, when such therapy is applied.

It thus would be desirable to provide a system of therapy which

- a) can remove materials deleterious to wound healing from wound exudate, whilst retaining materials that are beneficial in promoting wound healing in contact with the wound bed, and/or
- b) which allows fluids containing active amounts of materials that are beneficial in promoting wound healing to pass into and/or through the wound in contact with the wound bed.

Dialysis is a known method of treating bodily fluids such as blood ex vivo, to cleanse them of materials that are deleterious to the body systemically.

25

30

Retaining materials that are beneficial in some therapeutic aspect in the treated fluid is not an object of dialysis.

This method of treating bodily fluids is also a systemic therapy, since the treated fluid is returned to within the body.

This is in contrast to a topical therapy in which the treated fluid is recycled outside the body, e.g. to a wound.

Dialysis also requires large amounts either of bodily fluids, such as blood, or dialysate, and consequently the relevant devices tend not to be portable.

Even when in a highly exuding state, chronic wounds produce relatively little fluid to be treated and relatively little materials that are beneficial in some therapeutic aspect to be retained in the wound and/or its environment.

It is an object of the present invention

- a) to obviate at least some of the abovementioned disadvantages of known aspiration and/or irrigation therapy systems, and
- 20 b) to provide a system of therapy which
 - i) can remove materials deleterious to wound healing from wound exudate, whilst retaining materials that are beneficial in promoting wound healing in contact with the wound bed, and/or
 - ii) which allows fluids containing active amounts of materials that are beneficial in promoting wound healing to pass into and/or through the wound in contact with the wound bed.

It is a further object of the present invention

- a) to obviate at least some of the abovementioned disadvantages of known dialysis systems, and
- b) to provide a system of therapy which
 - i) can remove materials deleterious to wound healing from wound exudate, whilst retaining materials that are beneficial in promoting wound healing in contact with the wound bed, and
- ii) further allows fluids containing active amounts of materials that are beneficial in promoting wound to pass into and/or through the wound in contact with the wound bed,

WO 2005/105176

without affecting the body systemically.

It is a yet further object of the present invention

- a) to obviate at least some of the abovementioned disadvantages of known dialysis systems, and
- b) to provide a system of therapy which
 - i) can remove materials deleterious to wound healing from wound exudate, whilst retaining materials that are beneficial in promoting wound healing in contact with the wound bed, and
 - ii) further allows fluids containing active amounts of materials that are beneficial in promoting wound to pass into and/or through the wound in contact with the wound bed without affecting the body systemically, and
 - iii) is portable.

15

20

30

10

5

Additionally, known forms of wound dressing and aspiration and/or irrigation therapy systems often create a wound environment under the backing layer that may result in the loss of optimum performance of the body's own tissue healing processes, and slow healing and/or weak new tissue growth that does not have a strong three-dimensional structure adhering well to and growing from the wound bed. This is a significant disadvantage, in particular in chronic wounds.

It is an object of the present invention

- 25 a) to obviate at least some of the abovementioned disadvantages of known wound dressing, and
 - b) to provide a system of therapy which
 - i) can remove materials deleterious to wound healing from wound exudate, whilst retaining materials that are beneficial in promoting wound healing in contact with the wound bed, and
 - ii) which creates flow stress across the wound bed surface, e.g. a shear flow gradient, e.g. by passing irrigant and/or wound exudate through the wound in a controllable stream.
- Such a flow stress across a cell containing surface such as the wound bed, e.g. a shear flow gradient, has been found to result in effects that may be beneficial for wound healing.

4

These are effects such as, but not limited to an increase in cell proliferation, debridement of necrotic tissue, removal of slough and to allow alignment of collagen fibres.

This leads to improved breaking strength of tissue growth, to a strong threedimensional structure adhering well to and growing from the wound bed, and reduction of wound recurrence.

Removal of excess fluid assists with the reduction of interstitial oedema and pressure directly affecting the lymphatic and capillary system, restoring lymph function and stimulating blood flow.

Thus, according to a first aspect of the present invention there is provided an apparatus for irrigating, flow stressing and/or cleansing wounds, characterised in that it comprises

a) a fluid flow path, comprising

15

25

30

- i) a conformable wound dressing, having a backing layer which is capable of forming a relatively fluid-tight seal or closure over a wound and
- at least one inlet pipe for connection to a fluid supply tube, which passes through and/or under the wound-facing face, and and at least one outlet pipe for connection to a fluid offtake tube, which passes through and/or under the wound-facing face,
 - the point at which the or each inlet pipe and the or each outlet pipe passes through and/or under the wound-facing face forming a relatively fluid-tight seal or closure over the wound,
 - at least one inlet pipe being connected to a fluid recirculation tube, and at least one outlet pipe being connected to a fluid offtake tube: and
 - ii) a means for fluid cleansing having at least one inlet port connected to a fluid offtake tube and at least one outlet port connected to a fluid recirculation tube;
 - b) a fluid reservoir connected by a fluid supply tube to an integer of the flow path (optionally or as necessary via means for flow switching between supply and recirculation);
- 35 c) a device for moving fluid through the wound dressing and means for fluid cleansing, and optionally or as necessary the fluid supply tube; and

5

d) the apparatus having means for applying flow stress to the wound bed; and

e) means for bleeding the flowpath, such that fluid may be supplied to fill the flowpath from the fluid reservoir via the fluid supply tube (optionally or as necessary via the means for flow switching) and recirculated by the device through the flow path.

Where any pipe is described in connection with the apparatus as being connected or for connection to a (mating end of a) tube, e.g. a fluid supply tube, fluid recirculation tube or fluid offtake tube, the pipe and the tube may form a single integer in the flow path through which the circulating fluid from the wound passes.

The means for applying flow stress to the wound bed in the apparatus for aspirating, irrigating and/or cleansing a wound according to the first aspect of the present invention include means for applying, controlling and/or varying irrigant and/or wound exudate flow under the wound dressing as hereinbefore defined at any appropriate points across the wound bed.

20 These include

10

15

25

30

35

- features in the conformation of the wound dressing, in particular in the wound facing face of the dressing in relation to the wound bed in use, and/or
- b) features in the rest of the system in which the fluid recirculates, in particular the throughput of the device for moving fluid through the wound which give the appropriate or desired fluid flow rate or velocity of the irrigant and/or wound exudate under the wound dressing to cause flow stress at any appropriate points across the wound bed. These are described in detail hereinafter in connection with the operation of the apparatus.

It is sufficient to note here that features in the conformation of the wound dressing, in particular in the wound facing face of the dressing in relation to the wound bed in use, which give the appropriate or desired fluid flow rate or velocity of the irrigant and/or wound exudate under the wound dressing to cause flow stress at any appropriate points across the wound bed include irrigant inlet manifolds which contact or lie very close to the wound bed,

WO 2005/105176

5

20

25

6

PCT/GB2005/001588

irrigant inlet or outlet manifolds comprised in the dressing, which have apertures or pores by the wound bed that are of suitable total area over an extended area.

projections, such as bulges or protuberances on the wound-facing face of the dressing, that are capable of directing flow.

Features in the rest of the system in which the fluid recirculates, in particular the throughput of the device for moving fluid through the wound, which give the appropriate or desired fluid flow rate or velocity of the irrigant and/or wound exudate under the wound dressing to cause flow stress at any appropriate points across the wound bed include devices which impose relatively high flow rates or velocities, or rates of change in the flow rates or velocities, of irrigant and/or wound exudate flow under the wound dressing at any appropriate points across the wound bed, and/or

15 a relatively high pressure drop between the interior of an inlet manifolds comprised in the dressing and the wound bed.

Change in the flow velocities of irrigant and/or wound exudate flow under the wound dressing at any appropriate points across the wound bed include changes from positive to negative over the wound bed, i.e. reversing flow, in particular with relatively high rates of flow across the wound bed.

As noted hereinbefore, the present invention in this aspect advantageously provides a means for combining more than one therapy in a single dressing system, such as

- removal of materials deleterious to wound healing from wound exudate, whilst retaining materials that are beneficial in promoting wound healing, and
- b) promoting wound healing, by stimulating new tissue growth adhering well
 to and growing from the wound bed, by creating flow stress across the wound bed surface.

Such flow stress across the wound bed may also advantageously act against wound bacteria, by

- 35 a) breaking up biofilm growth before it develops a strong three-dimensional structure adhering well to and growing from the wound bed and/or
 - b) releasing them to be attacked by the body in the wound.

7

It may aid in the debridement of slough, eschar and necrotic tissue growth from the wound, and in preventing adhesion of wound tissue to the dressing.

Examples of suitable ways in which flow stress can be achieved include applying

- a) an optionally varying and/or reversing linear flow and/or
- b) a relatively high rate of irrigant flow across the area of the wound bed.
- 10 That is, flow stress across the wound may be provided by means of
 - a) a linear flow of irrigant across the wound bed,
 - b) a relatively high rate of irrigant flow across the wound bed, or
 - c) a combination of the two.

5

25

30

35

When used herein, the term 'linear' refers to flow that is locally linear on a cellular scale, and thus includes not only parallel flow, but also radial streaming, and spiral, helical, spirohelical and circular streaming. Preferred linear flows include radial streaming from the centre out and from the periphery in to centre, in particular from the periphery in to the centre as this may increase the cell motility velocity of keratinocytes towards the centre, and so promote re-epithelialisation.

It is also preferred that the flow rate is relatively uniform across the wound to achieve a uniform stimulation applied across the wound bed.

The velocity of the fluid thereover may be constant, but it may be varied, preferably cyclically, either randomly or regularly. Usually the direction of the wound irrigant and/or wound exudate is held constant, but the flow rate may be varied positively and negatively, preferably cyclically, and either randomly or regularly.

Cyclical application of flow stress across the wound bed may result in a further increase in cell proliferation and in the breaking strength of tissue growth, and in a strong three-dimensional structure of tissue adhering well to and growing from the wound bed.

30

35

The stimulation of the healing of wounds in the present invention may also be effected by regularly or randomly pulsing a flow velocity applied to the wound at any appropriate point for this purpose.

- 5 The frequencies of such pulsed flow stressing across the wound will be
 - a) substantially higher than those of the cycles of flow velocity to the wound bed for the stimulation of the healing of wounds referred to above, but
- b) substantially less than the frequencies of ultrasound used on the
 wound bed conventionally

Pulsing the flow over the wound may advantageously also provide a means to over-ride pain, similar to TENS

15 Stimulus to the wound bed by applying an optionally varying flow velocity and agitation of the wound bed to stimulate the cells by regularly or randomly pulsing any flow applied to the wound are mutually compatible. They may, as appropriate, be applied alone or together. Flow may be applied continually or in periodic episodes between which the apparatus is operating in lower flow regimes

Thus, an embodiment of the apparatus for irrigating, flow stressing and/or cleansing wounds of the present invention is characterised in that it comprises means for supplying optionally varying linear flow velocity, which is optionally pulsed, to a wound bed for the stimulation of the healing of the wound.

Examples of suitable linear velocities are up to 0.03 m/s in a 100 micrometre gap or channel between wound bed and dressing creating a shear stress on the wound bed of the order of 12 - 13 dynes/cm². In practice, such a velocity will be of the order of 0.06 to 6, e.g. 0.2 to 2, for example 0,6 mm/s in a 100 micrometer channel between wound bed and dressing creating a shear stress on the wound bed of the order of 0.06 to 20, e.g. 0.6 to 6, for example 0.6 - 2 dynes/cm², for a typical wound exudate and/or isotonic saline irrigant.

By way of example, a fluid velocity of e.g. 0.3 m/s will typically be a flow rate of 70 - 200 ml/hr for a 100 mm diameter wound.

It will be appreciated that the shear stress on the wound bed will increase with the viscosity of the fluid passing across it. This property may be used to increase or decrease the flow stress generated by a given flow velocity.

Another embodiment of the apparatus for irrigating, flow stressing and/or cleansing wounds of the present invention is characterised in that it comprises means for supplying optionally varying relatively high flow velocity, which is optionally pulsed, to a wound bed for the stimulation of the healing of the wound.

10

20

25

30

As noted hereinbefore, in the present invention in this aspect, the flow velocity of the fluid may be constant, but may be varied, preferably cyclically, either randomly or regularly. In both embodiments:

Examples of suitable frequencies of such regular cycles of flow velocities for the stimulation of the healing of wounds include 1 to 48 per 24hr.

Examples of preferred frequencies of such regular cycles of flow velocities for the stimulation of the healing of wounds include 12 to 24 per 24hr, e.g. 2 to 1 per hr.

Examples of suitable waveforms of such cycles either regularly or randomly for the stimulation of the healing of wounds include curved, e.g. sinusoidal, and sawtooth for higher frequencies, and usually square for lower frequencies.

Examples of means for applying flow stress to the wound bed include supplying irrigant to, and letting out irrigant and/or wound exudate from, the wound dressing in regular or random cycles and/or pulsed either regularly or randomly.

Examples of suitable frequencies of such regular pulses for the stimulation of the healing of wounds include 1 to 60 per min, e.g. 5 to 10 per min.

Examples of preferred frequencies of such regular pulses for the stimulation of the healing of wounds include 30 to 60 per min, e.g. 10 to 20 per min.

Examples of suitable waveforms of such pulses either regularly or randomly for the stimulation of the healing of wounds include curved, e.g. sinusoidal, sawtooth, square and a systolic-diastolic asymmetric sawtooth.

Examples of means for applying an optionally varying linear flow velocity at any appropriate point for flow stressing the wound include a wound dressing as hereinbefore defined that comprises one or more modules capable of imposing linear flow on the irrigant at any appropriate point across the wound bed.

10

15

Thus, one favoured embodiment of the apparatus for irrigating, stressing and/or cleansing wounds is characterised in that it comprises a wound dressing as hereinbefore defined that comprises one or more modules capable of imposing linear flow on the irrigant across the wound bed at any appropriate point for flow stressing the wound.

Examples of suitable modules capable of imposing linear flow on the irrigant across the wound bed at any appropriate point for stressing the wound include the following in conjunction with a wound-facing face of the dressing that is in contact with or very close to the wound bed:

A plurality of inlet and/or outlet pipes disposed in an array under the woundfacing face of the dressing, so as to allow passage of irrigant and/or wound exudate through the wound to take place in a controllable linear stream.

25

30

35

20

Irrigant inlet and/or outlet manifolds with respectively a plurality of inlet and/or outlet apertures, and connected in turn to at least one irrigant inlet pipe(s) and/or outlet pipe(s) under the wound-facing face of the wound dressing. (Fluid passes between these structures and they assist in channelling flow of irrigant and/or wound exudate through the wound in a controllable stream.) These may include tubules in an array connecting into a manifold.

Projections, such as bulges or protruberances, effectively on the wound-facing face of the dressing. Alternatively or additionally, where appropriate depressions effectively on the wound-facing face of the dressing.

11

Both will often run within the wound between the inlet pipe(s) and the outlet pipe(s) under the wound-facing face of the wound dressing.

Fluid-inflatable bodies that lie in the wound in use and form projections are described hereinafter in greater detail.

Of particular interest are fluid-inflatable irrigant inlet manifolds comprised in the dressing, which are inflated by admitting irrigant fluid.

10 Examples of preferred such modules include fluid-inflatable irrigant inlet manifolds comprised in the dressing as described hereinafter in greater detail.

The modules and backing layer may be completely separate integers, separate integers which are attached, for example by heat sealing, to each other, or they may be integral, i.e. may be formed of a single piece of material.

In all cases the modules may be disposed to impose linear flow between the inlet pipe(s) and the outlet pipe(s) under the wound-facing face of the wound dressing, as hereinbefore describe, in a number of different modes.

Examples of forms of linear flow imposed on the irrigant across the wound bed at any appropriate point for stressing the wound include not only parallel flow, but also radial streaming, and spiral, helical, spirohelical and circular streaming. Preferred linear flows include radial streaming. Preferred linear flows include radial streaming from the centre out and from the periphery in to centre, in particular from the periphery in to the centre as this may increase the cell motility velocity of keratinocytes towards the centre, and so promote re-epithelialisation.

25

30

35

Thus, the modules may comprise a plurality of inlet and/or outlet pipes disposed in an array under the wound-facing face of the dressing, so as to allow passage of irrigant and/or wound exudate through the wound to take place in a controllable linear stream.

Two arrays of inlet pipe(s) and/or outlet pipe(s) under the wound-facing face of the wound dressing may be aligned parallel to each other, opposing each other diametrically across the wound, so that when fluid passes between these structures they assist in channelling flow of irrigant and/or wound exudate across the wound in a parallel stream.

12

PCT/GB2005/001588

Preferably, a plurality of inlet pipe(s) or outlet pipe(s) is disposed to surround respectively one or more centrally disposed outlet or inlet pipes. (These may be at the geometric centre of the backing layer of the wound dressing as hereinbefore defined, rather than generally centrally disposed therein.) The purpose is to allow passage of irrigant and/or wound exudate through the wound to take place in a controllable radial stream.

As above, such a stream applies flow stress radially across the wound bed.

15

10

5

WO 2005/105176

The plurality of inlet and/or outlet apertures respectively in irrigant inlet and/or outlet manifolds, connected in turn to at least one irrigant inlet pipe(s) and/or outlet pipe(s) under the wound dressing are equivalent to the above plurality of inlet pipe(s) or outlet pipe(s).

20

30

Again, the purpose is to allow passage of irrigant and/or wound exudate through the wound to take place in a controllable linear stream.

As above, such irrigant inlet and/or outlet manifolds may be aligned parallel to each other, opposing each other diametrically across the wound, so that when fluid passes between these structures they assist in channelling flow of irrigant and/or wound exudate across the wound in a parallel stream.

Preferably, an irrigant inlet and/or outlet manifold with respectively a plurality of inlet and/or outlet apertures is disposed to surround respectively at least one more-centrally disposed outlet or inlet pipes. (These may be at the geometric centre of the backing layer of the wound dressing as hereinbefore defined, rather than generally centrally disposed therein.)

Preferably, an irrigant outlet and/or inlet manifold with respectively a plurality of inlet and/or outlet apertures is connected respectively to the at least one more-centrally disposed outlet or inlet pipes.

13

The purpose in both cases is to allow passage of irrigant and/or wound exudate through the wound to take place in a controllable radial stream. As above, such a stream applies flow stress radially across the wound bed.

As noted above, such irrigant inlet manifolds may be fluid-inflatable bodies that lie in the wound in use and form projections, as described hereinafter in greater detail.

These are inflated by admitting irrigant fluid, and they assist in channelling flow of irrigant and/or wound exudate through the wound.

In all such cases of radial streaming, the surrounding apertures could be at or near the periphery of the wound-facing face of the dressing, and the more-centrally disposed apertures could be at or near the centre. However, each are often disposed regularly or irregularly across the dressing, in the manner of a shower-head, and they are preferably disposed regularly across it, as this favours a constant flow rate over all parts of the wound bed.

Thus, according to another embodiment of the first aspect of the present invention there is provided a apparatus for irrigating and/or cleansing wounds, characterised in that it comprises a conformable wound dressing as hereinbefore defined having at least one (and preferably a plurality) of inlet or outlet apertures more-centrally disposed therein and a plurality of respectively outlet or inlet apertures disposed to surround the more-centrally disposed apertures.

The apertures may include the outlets of tubules an array connecting into a manifold. More usually, however, in all embodiments comprising such manifolds, they are formed of porous film or microporous membrane.

30

35

15

20

25

The apertures or pores by the wound bed are preferably distributed evenly over the underside of the dressing and/or over the wound bed in use. To achieve a relatively high flow rate, and depending on the appropriate or desired flow rate, of the moving fluid over the wound bed, the apertures or pores by the wound bed may suitably form of the order of 0.5 to 30% of the area of the wound-facing face of the dressing by the wound bed, such as 0.7 to 10%, e.g. 0.9 to 3%, for example about 1%.

WO 2005/105176

They may have an average cross-dimension of 1 to $1000\mu m$, such as 3 to $300\mu m$, e.g. 5 to $100\mu m$, for example 6 to $60\mu m$.

To the same end, in the present invention, the pressure differential across the porous film or microporous membrane with the apertures or pores by the wound bed on the underside of the dressing in use may suitably be of the order of 1 to 500 mmHg, such as 3 to 250 mmHg, e.g.10 to 125 mmHg, for example about 80 mmHg.

Alternatively or additionally, where appropriate there may be projections, such as bulges or protruberances, and/or where appropriate depressions, effectively on the wound-facing face of the dressing. Both will often run within the wound between the inlet pipe(s) and the outlet pipe(s) under the wound-facing face of the wound dressing. (Fluid passes between these structures and they assist in channelling flow of irrigant and/or wound exudate through the wound in a controllable stream.)

The projections may have a significantly three-dimensional structure, such as points, bosses, ribs and ridges.

20

30

35

5

Such bosses may be circular, elliptical or polygonal in plan view, such as triangular, rectangular or hexagonal.

These may be may be, e.g. an integral net with elongate apertures e.g. formed by fibrillation of an embossed film, sheet or membrane of a polymeric material or by casting the material.

These are preferably projections in a substantially radiating array under the wound-facing face of the wound dressing. The projections may be disposed regularly or irregularly across the dressing, although they are often disposed regularly across it.

Again, the depressions may have a significantly three-dimensional structure, such as grooves, channels or conduits. In all cases, the structures are preferably in a substantially radial array. Suitably, these may be formed by embossing a sheet, film or membrane.

15

Fluid-inflatable bodies that lie in the wound in use may form such projections, in particular such inlet manifolds, as described hereinafter in greater detail. These are inflated by admitting irrigant fluid, and they assist in channelling flow of irrigant and/or wound exudate through the wound in a controllable stream. As noted above, they may be formed of porous film or microporous membrane.

The inflated manifolds may have a significantly three-dimensional structure, such as points, bosses, ribs and ridges. Such bosses may be circular, elliptical or polygonal in plan view, such as triangular, rectangular or hexagonal.

The backing layer and modules may be of the same or different materials, but each should be of a material that does not absorb aqueous fluids such as water, blood, wound exudate, etc. and is soft and resiliently deformable.

According to another embodiment of the first aspect of the present invention there is provided a apparatus for irrigating and/or cleansing wounds, characterised in that it comprises a conformable wound dressing as hereinbefore defined having projecting or depressed structures disposed between the inlet pipe(s) and the outlet pipe(s) under the wound-facing face of the wound dressing.

In the embodiment of the apparatus that is characterised in that it comprises means for supplying optionally varying flow velocity, which is optionally pulsed, to a wound bed for the stimulation of the healing of the wound, the relatively high flow rates are typically provided by the device for moving fluid through the wound and means for fluid cleansing.

The type and/or capacity of a suitable device for moving fluid through the wound at the desired velocity will be largely determined by the appropriate or desired fluid flow rate and the flow resistance of the flow path.

Suitable devices are indicated below.

5

10

15

20

25

25

35

As noted hereinbefore, in all embodiments of this aspect of the present invention, the flow velocity of the fluid may be constant, but may be varied, preferably cyclically, either randomly or regularly.

To achieve this, the present apparatus additionally, where appropriate, comprises a system which can regulate the pump output to the wound bed under the wound dressing.

Preferably such a system is a conventional automated, programmable system which can maintain the wound at or near an appropriate, desired flow stress to the wound bed to an 'd by regularly or randomly pulsing a flow velocity applied to the wound at any appropriate point for this purpose.

Such pulsed flow across the wound may be provided by some types of the device for moving fluid through the wound and means for fluid cleansing.

Certain diaphragm pumps described hereinafter in greater detail will be appropriate for this purpose, as are peristaltic pumps, an electrically pulsable valve on the fluid reservoir, and an electromechanical oscillator directly coupled to the wound dressing.

In all embodiments of the apparatus of this first aspect of the present invention for aspirating, irrigating and/or cleansing wounds, a particular advantage is the tendency of the wound dressing to conform to the shape of the bodily part to which it is applied.

The wound dressing comprises a backing layer with a wound-facing face which is capable of forming a relatively fluid-tight seal or closure over a wound and

at least one inlet pipe for connection to a fluid supply tube or recirculation tube, which passes through and/or under the wound-facing face, and and at least one outlet pipe for connection to a fluid offtake tube, which passes through and/or under the wound-facing face,

the point at which the or each inlet pipe and the or each outlet pipe passes through and/or under the wound-facing face forming a relatively fluid-tight seal or closure.

17

The term 'relatively fluid-tight seal or closure' is used herein to indicate one which is fluid- and microbe-impermeable and permits a positive or negative pressure of up to 50% atm., more usually up to 15% atm. to be applied to the wound. The term 'fluid' is used herein to include gels, e.g. thick exudate, liquids, e.g. water, and gases, such as air, nitrogen, etc.

The shape of the backing layer that is applied may be any that is appropriate to aspirating, irrigating and/or cleansing the wound across the area of the wound.

10

20

25

30

5

Examples of such include a substantially flat film, sheet or membrane, or a bag, chamber, pouch or other structure of the backing layer, e.g. of polymer film, which can contain the fluid.

The backing layer may be a film, sheet or membrane, often with a (generally uniform) thickness of up to 100 micron, preferably up to 50 micron, more preferably up to 25 micron, and of 10 micron minimum thickness.

Its largest cross-dimension may be up to 500 mm (for example for large torso wounds), up to 100 mm (for example for axillary and inguinal wounds), and up to 200 mm for limb wounds (for example for chronic wounds, such as venous leg ulcers and diabetic foot ulcers.

Desirably the dressing is resiliently deformable, since this may result in increased patient comfort, and lessen the risk of inflammation of a wound.

Suitable materials for it include synthetic polymeric materials that do not absorb aqueous fluids, such as polyolefins, such as polyethylene e.g. high-density polyethylene, polypropylene, copolymers thereof, for example with vinyl acetate and polyvinyl alcohol, and mixtures thereof; polysiloxanes; polyesters, such as polycarbonates; polyamides, e.g. 6 - 6 and 6 - 10 polyamides, and hydrophobic polyurethanes.

They may be hydrophilic, and thus also include hydrophilic polyurethanes.

WO 2005/105176 PCT/GB2005/001588

They also include thermoplastic elastomers and elastomer blends, for example copolymers, such as ethyl vinyl acetate, optionally or as necessary blended with high-impact polystyrene.

5 They further include elastomeric polyurethane, particularly polyurethane formed by solution casting.

Preferred materials for the present wound dressing include thermoplastic elastomers and curable systems.

10

30

The backing layer is capable of forming a relatively fluid-tight seal or closure over the wound and/or around the inlet and outlet pipe(s).

However, to prevent maceration of the skin around the wound, it is preferably of a material that has a high moisture vapour permeability, in particular around the periphery of the wound dressing, outside the seal. It may also be a switchable material that has a higher moisture vapour permeability when in contact with liquids, e.g. water, blood or wound exudate. This may, e.g. be a material that is used in Smith & Nephew's Allevyn™, IV3000™ and OpSite™ dressings.

The periphery of the wound-facing face of the backing layer may bear an adhesive film, for example, to attach it to the skin around the wound.

This may, e.g. be a pressure-sensitive adhesive, if that is sufficient to hold the wound dressing in place in a fluid-tight seal around the periphery of the wound-facing face of the wound dressing.

Alternatively or additionally, where appropriate a light switchable adhesive could be used to secure the dressing in place to prevent leakage. (A light switchable adhesive is one the adhesion of which is reduced by photocuring. Its use can be beneficial in reducing the trauma of removal of the dressing.)

Thus, the backing layer may have a flange or lip extending around the proximal face of the backing layer, of a transparent or translucent material (for which it will be understood that materials that are listed above are amongst those that are suitable).

WO 2005/105176 PCT/GB2005/001588

This bears a film of a light switchable adhesive to secure the dressing in place to prevent leakage on its proximal face, and a layer of opaque material on its distal face.

- To remove the dressing and not cause excessive trauma in removal of the dressing, the layer of opaque material on the distal face of the flange or lip extending around the proximal wound is removed prior to application of radiation of an appropriate wavelength to the flange or lip.
- 10 If the periphery of the wound dressing, outside the relatively fluid-tight seal, that bears an adhesive film to attach it to the skin around the wound, is
 - a) of a material that has a high moisture vapour permeability or
 - b) is a switchable material,
- then the adhesive film, if continuous, should also have a high or switchable moisture vapour permeability, e.g. be an adhesive such as used in Smith & Nephew's Allevyn™, IV3000™ and OpSite™ dressings.
- Where a vacuum, is applied to hold the wound dressing in place in a fluidtight seal around the periphery of the wound-facing face of the wound dressing, the wound dressing may be provided with a silicone flange or lip to seal the dressing around the wound. This removes the need for adhesives and associated trauma to the patient's skin.
- Where the interior of, and the flow of irrigant and/or wound exudate to and through, the dressing is under any significant positive pressure, which will tend to act at peripheral points to lift and remove the dressing off the skin around the wound.
- In such use of the apparatus, it may thus be necessary to provide means for forming and maintaining such a seal or closure over the wound against such positive pressure on the wound, to act at peripheral points for this purpose.
- Examples of such means include light switchable adhesives, as above, to secure the dressing in place to prevent leakage.

WO 2005/105176 PCT/GB2005/001588

Since the adhesion of a light switchable adhesive is reduced by photocuring, thereby reducing the trauma of removal of the dressing, a film of a more aggressive adhesive may be used, e.g. on a flange, as above.

Examples of suitable fluid adhesives for use in more extreme conditions where trauma to the patient's skin is tolerable include ones that consist essentially of cyanoacrylate and like tissue adhesives, applied around the edges of the wound and/or the proximal face of the backing layer of the wound dressing, e.g. on a flange or lip.

10

20

25

35

Further suitable examples of such means include adhesive (e.g. with pressure-sensitive adhesive) and non-adhesive, and elastic and non-elastic straps, bands, loops, strips, ties, bandages, e.g. compression bandages;

sheets, covers, sleeves, jackets, sheathes, wraps, stockings and hose, e.g. elastic tubular hose or elastic tubular stockings that are a compressive fit over a limb wound to apply suitable pressure to it when the therapy is applied in this way; and

inflatable cuffs, sleeves, jackets, trousers, sheathes, wraps, stockings and hose that are a compressive fit over a limb wound to apply suitable pressure to it when the therapy is applied in this way.

Such means may each be laid out over the wound dressing to extend beyond the periphery of the backing layer of the wound dressing, and as appropriate will be adhered or otherwise secured to the skin around the wound and/or itself and as appropriate will apply compression (e.g. with elastic bandages, stockings) to a degree that is sufficient to hold the wound dressing in place in a fluid-tight seal around the periphery of the wound,

30 Such means may each be integral with the other components of the dressing, in particular the backing layer.

Alternatively, it may be permanently attached or releasably attached to the dressing, in particular the backing layer, with an adhesive film, for example, or these components may be a Velcro ™, push snap or twist-lock fit with each other.

21

The means and the dressing may be separate structures, permanently unattached to each other.

In a more suitable layout for higher positive pressures on the wound, a stiff flange or lip extends around the periphery of the proximal face of the backing layer of the wound dressing as hereinbefore defined.

The flange or lip is concave on its proximal face to define a peripheral channel or conduit.

10

20

25

30

35

It has a suction outlet that passes through the flange or lip to communicate with the channel or conduit and may be connected to a device for applying a vacuum, such as a pump or a piped supply of vacuum.

The backing layer may be integral with or attached, for example by heatsealing, to the flange or lip extending around its proximal face.

To form the relatively fluid-tight seal or closure over a wound that is needed and to prevent passage of irrigant and/or exudate under the periphery of the wound-facing face of the wound dressing, in use of the apparatus, the dressing is set on the skin around the wound.

The device then applies a vacuum to the interior of the flange or lip, thus forming and maintaining a seal or closure acting at peripheral points around the wound against the positive pressure on the wound.

With all the foregoing means of attachment, and means for forming and maintaining a seal or closure over the wound, against positive or negative pressure on the wound at peripheral points around the wound, the wound dressing sealing periphery is preferably of a generally round shape, such as an ellipse, and in particular circular.

To form the relatively fluid-tight seal or closure over a wound and around the inlet pipe(s) and outlet pipe(s) at the point at which they pass through and/or under the wound-facing face, the backing layer may be integral with these other components.

The components may alternatively just be a push, snap or twist-lock fit with each other, or adhered or heat-sealed together.

The or each inlet pipe or outlet pipe may be in the form of an aperture, such as a funnel, hole, opening, orifice, luer, slot or port for connection as a female member respectively to a mating end of

a fluid recirculation tube and/or fluid supply tube (optionally or as necessary via means for forming a tube, pipe or hose, or nozzle) or

a fluid offtake tube.

10

Where the components are integral they will usually be made of the same material (for which it will be understood that materials that are listed above are amongst those that are suitable).

Where, alternatively, they are a push, snap or twist-lock fit, the may be of the same material or of different materials. In either case, materials that are listed above are amongst those that are suitable for all the components.

The or each pipe will generally pass through, rather than under the backing layer. In such case, the backing layer may often have a rigid and/or resiliently inflexible or stiff area to resist any substantial play between the or each pipe and the or each mating tube, or deformation under pressure in any direction.

It may often be stiffened, reinforced or otherwise strengthened by a boss projecting distally (outwardly from the wound) around each relevant tube, pipe or hose, or nozzle, hole, opening, orifice, luer, slot or port for connection to a mating end of a fluid recirculation tube and/or fluid supply tube or fluid offtake tube.

.30

Alternatively or additionally, where appropriate the backing layer may have a stiff flange or lip extending around the proximal face of the backing layer to stiffen, reinforce or otherwise strengthen the backing layer.

To be suitable for use, in particular to impose linear flow, the wound facing face of the dressing should contact or lie very close to the wound bed.

WO 2005/105176

In particular with relatively high concentrations of materials that are deleterious to wound healing, it may be advantageous to provide a system where wound irrigant and/or wound exudate may be distributed more evenly, or pass in a more linear path under the dressing over the wound bed.

5

10

Accordingly, one form of the dressing is provided with pipes, tubes or tubules that radiate from an inlet manifold to the wound bed to end in apertures and deliver the circulating fluid directly towards the periphery of the wound bed via the apertures. Similarly, there is an outlet manifold towards or at the centre of the wound bed in which openings collect the return fluid directly from the wound bed. The inlet and outlet manifolds may of course be arranged vice versa.

The pipes, etc. may radiate regularly or irregularly through the wound in use, respectively from the inlet or outlet manifold, although regularly may be preferred. They may serve to channel the flow radially across the wound bed.

Other suitable forms of layout of the pipes, etc. include one which has pipes, tubes or tubules extending radially from the inlet pipe(s) and/or outlet pipe(s) at the point at which they pass through and/or under the wound-facing face of the backing layer to run over the wound bed.

These may have a blind bore with perforations, apertures, holes, openings, orifices, slits or slots along the pipes, etc.

These pipes, etc. then effectively form an inlet pipe manifold that delivers the circulating fluid directly to the wound bed or outlet pipe or collects the fluid directly from the wound respectively.

30

It does so via the holes, openings, orifices, slits or slots in the tubes, pipes, tubules, etc. over most of the wound bed under the backing layer.

It may be desirable that the tubes, pipes or tubules are resiliently flexible, e.g. elastomeric, and preferably soft, structures with good conformability in the wound and the interior of the wound dressing.

24

As also mentioned herein, the backing layer that is applied may be any that is appropriate to the present system of therapy and permits a positive or negative pressure of up to 50% atm., more usually up to 25% atm. to be applied to the wound.

5

15

25

It is thus often a microbe-impermeable film, sheet or membrane, which is substantially flat, depending on any pressure differential on it.

It often has a (generally uniform) thickness similar to such films or sheets used in conventional wound dressings, i.e. up to 100 micron, preferably up to 50 micron, more preferably up to 25 micron, and of 10 micron minimum thickness.

The backing layer may often have a rigid and/or resiliently inflexible or stiff area to resist any substantial play between other components that are not mutually integral, and may be stiffened, reinforced or otherwise strengthened, e.g. by a projecting boss.

Such a form of dressing would not be very conformable to the wound bed, 20 and may effectively form a chamber, hollow or cavity defined by a backing layer and the wound bed under the backing layer.

As noted above, the interior of the wound dressing should conform to the wound bed, even for a wound in a highly exuding state. Accordingly, one form of the dressing is provided with a wound filler under the backing layer.

This is favourably a resiliently flexible, e.g. elastomeric, and preferably soft, structure with good conformability to wound shape.

30 It is urged by its own resilience against the backing layer to apply gentle pressure on the wound bed.

The wound filler may be integral with the other components of the dressing, in particular the backing layer.

WO 2005/105176

Alternatively, it may be permanently attached to them/it, with an adhesive film, for example, or by heat-sealing, e.g. to a flange or lip extending from the proximal face, so a not to disrupt the relatively fluid-tight seal or closure over the wound that is needed.

5

15

20

25

Less usually, the wound filler is releasably attached to the backing layer, with an adhesive film, for example, or these components may be a push, snap or twist-lock fit with each other.

10 The wound filler and the backing layer may be separate structures, permanently unattached to each other.

The wound filler may be or comprise a solid integer, favourably a resiliently flexible, e.g. elastomeric, and preferably soft, structure with good conformability to wound shape.

Examples of suitable forms of such wound fillers are foams formed of a suitable material, e.g. a resilient thermoplastic. Preferred materials for the present wound dressing include reticulated filtration polyurethane foams with small apertures or pores.

Alternatively or additionally, it may be in the form of, or comprise one or more conformable hollow bodies defined by a film, sheet or membrane, such as a bag, chamber, pouch or other structure, filled with a fluid or solid that urges it to the wound shape.

The film, sheet or membrane, often has a (generally uniform) thickness similar to that of films or sheets used in conventional wound dressing backing layers.

30

That is, up to 100 micron, preferably up to 50 micron, more preferably up to 25 micron, and of 10 micron minimum thickness, and is often resiliently flexible, e.g. elastomeric, and preferably soft.

35 Such a filler is often integral with the other components of the dressing, in particular the backing layer, or permanently attached to them/it, with an adhesive film, for example, or by heat-sealing, e.g. to a flange

26

Examples of suitable fluids contained in the hollow body or bodies defined by a film, sheet or membrane include gases, such as air, nitrogen and argon, more usually air, at a small positive pressure above atmospheric; and liquids, such as water, saline.

5

Examples also include gels, such as silicone gels, or preferably cellulosic gels, for example hydrophilic cross-linked cellulosic gels, such as Intrasite TM cross-linked materials.

- Examples also include aerosol foams, where the gaseous phase of the aerosol system is air or an inert gas, such as nitrogen or argon, more usually air, at a small positive pressure above atmospheric; foams, e.g. CaviCare™ foam; and solid particulates, such as plastics crumbs.
- Of course, if the backing layer is a sufficiently conformable and/or e.g. an upwardly dished sheet, the backing layer may lie under the wound filler, rather than vice versa.

In this type of layout, in order for the wound filler to urge the wound dressing towards the wound bed, it will usually have to be firmly adhered or otherwise releasably attached to the skin around the wound.

This is especially the case in those embodiments where the wound filler and the backing layer are separate structures, permanently unattached to each other.

In such a layout for deeper wounds when the therapy is applied in this way, the means for such attachment may also form and maintain a seal or closure over the wound.

30

25

Where the filler is over the backing layer, and the fluid inlet pipe(s) and outlet pipe(s) pass through the wound-facing face of the backing layer, they may run through or around the wound filler over the backing layer.

27

One form of the dressing is provided with a wound filler under the backing layer that is or comprises a resiliently flexible, e.g. elastomeric, and preferably soft, hollow body defined by a film, sheet or membrane, such as a bag, chamber, pouch or other structure, with apertures, holes, openings, orifices, slits or slots, or tubes, pipes, tubules or nozzles. It communicates with at least one inlet or outlet pipe through at least one aperture, hole, opening, orifice, slit or slot.

The fluid contained in the hollow body may then be the circulating fluid in the apparatus.

The hollow body or each of the hollow bodies then effectively forms an inlet pipe or outlet pipe manifold that delivers the circulating fluid directly to the wound bed or collects the fluid directly from the wound respectively via the holes, openings, orifices, slits or slots, or the tubes, pipes or hoses, etc. in the film, sheet or membrane.

When the therapy is applied in this way, the type of the filler may also be largely determined by the depth and/or capacity of the wound.

20

25

30

35

15

5

Thus, for shallower wounds, examples of suitable wound fillers as a component of a wound dressing include ones that consist essentially of one or more conformable hollow bodies defining an inlet pipe and/or outlet pipe manifold that delivers the circulating fluid directly to the wound bed or collects the fluid directly from the wound.

A more suitable wound filler for deeper wounds when the therapy is applied in this way may be one which comprises one or more conformable hollow bodies defined by, for example a polymer film, sheet or membrane, that at least partly surround(s) a solid integer. This may provide a system with better rigidity for convenient handling.

The wound filler under the backing layer may effectively form an inlet pipe or outlet pipe manifold with a direct connection between the inlet pipe(s) and outlet pipe(s) at the point at which they pass through and/or under the wound-facing face and the wound bed.

28

If it does not, in order for aspiration and/or irrigation of the wound bed to occur, it is appropriate for one or more bores, channels, conduits, passages, pipes, tubes, tubules and/or spaces, etc. to run from the point at which the fluid inlet pipe(s) and outlet pipe(s) pass through and/or under the wound-facing face of the backing layer through or around the wound filler under the backing layer.

5

10

15

20

25

30

35

Less usually, the wound filler is an open-cell foam with pores that may form such bores, channels, conduits, passages and/or spaces through the wound filler under the backing layer.

Where the filler is or comprises one or more conformable hollow bodies defined by, for example a polymer film, sheet or membrane, it may be provided with means for admitting fluids to the wound bed under the wound dressing.

These may be in the form of pipes, tubes, tubules or nozzles running from the point at which the fluid inlet pipe(s) and outlet pipe(s) pass through and/or under the wound-facing face of the backing layer through or around the wound filler under the backing layer.

All of the suitable layouts for shallower wounds that comprise blind-bore, perforated inlet pipe or outlet pipe manifolds that circulate fluid in the wound when the dressing is in use, that are described hereinbefore, may be used under a wound filler under the backing layer.

In brief, suitable layouts include ones where one or both manifolds are annular or toroidal (regular, e.g. elliptical or circular, or irregular), optionally with blind-bore, perforated radial tubes, pipes or nozzles, radiating from the annulus or torus.

The inlet and/or outlet tubes, the fluid recirculation tube and the fluid supply tube, etc. may be of conventional type, e.g. of elliptical or circular cross-section, and may suitably have a uniform cylindrical bore, channel, conduit or passage throughout their length.

Depending on the desired fluid volume flow rate of irrigant and/or wound exudate from the wound, and the desired amount in recirculation, suitably the largest cross-dimension of the bore may be up to 10 mm for large torso wounds, and up to 2 mm for limb wounds.

5

10

The tube walls should suitably thick enough to withstand any positive or negative pressure on them, in particular if the volume of irrigant and/or wound exudate from the wound in recirculation is increased by continuing addition to it of wound exudate, and/or fluid passing from a cleansing fluid through a selectively permeable integer, for example the polymer film, sheet or membrane of a two-phase system, such as an dialysis unit. However, as noted below with regard to pumps, the prime purpose of such tubes is to convey fluid irrigant and exudate through the length of the apparatus flow path, rather than to act as pressure vessels. The tube walls may suitably be at least 25 micron thick.

The bore or any perforations, apertures, holes, openings, orifices, slits or slots along the pipes, etc. or in the hollow body or each of the hollow bodies may be of small cross-dimension.

20

15

They may then effectively form a macroscopic and/or microscopic filter for particulates including cell debris and micro-organisms, whilst allowing proteins and nutrients to pass through.

- Such tubes, pipes or hoses, etc. through and/or around the filler, whether the latter is a solid integer and/or one or more resiliently flexible or conformable hollow bodies, are described in further detail hereinbefore in connection with the inlet pipe(s) and outlet pipe(s).
- 30 As regards the apparatus as a whole, the means for flow switching between supply and recirculation may take any form that enables the wound simultaneously to be
 - a) put into communication with the fluid reservoir but
 - b) closed to the fluid recirculation tube, and
- 35 c) vice versa.

Thus, if there is only one inlet pipe that passes through and/or under the wound-facing face of the wound dressing, the fluid reservoir is connected by the fluid supply tube to the flow path via means for flow switching as desired the into a fluid recirculation tube or a fluid offtake tube.

5

In this case, the means for flow switching between supply and recirculation may be a regulator, such as a T- valve.

10

This is connected in turn to two parts of a fluid recirculation tube or a fluid offtake tube and the fluid supply tube, such that the desired flow switching between supply and recirculation is achieved.

15

If there are two or more inlet pipes, these may be connected respectively to a fluid supply tube or fluid recirculation tube, respectively having a first regulator and a second regulator, such as a valve or other control device for admitting fluids into the wound.

20

The desired flow switching between supply and recirculation is achieved by respectively having the first regulator open when the second regulator is shut, and vice versa.

The means for bleeding the flowpath may be situated in any appropriate part of the apparatus that is in contact with the irrigant and/or wound exudate, but is usually within the offtake and/or recirculation tubes.

25

However, it is often as far downstream of and away from the reservoir and the fluid supply tube as possible, so that it may be used to prime the whole of the flowpath from the fluid reservoir via the fluid supply tube.

30

It may be a regulator, such as a valve or other control device, e.g. a T-valve that is turned to switch between bleed and recirculation, for bleeding fluids from the apparatus, e.g. to a waste reservoir, such as a collection bag.

35

Alternatively, flow switching between supply and recirculation may not be desired, but rather concomitant bleeding and/or recirculation is desired. The latter may occur when the volume of irrigant and/or wound exudate in recirculation is increased by continuing addition to it of

- a) wound exudate, and/or
- b) fluid passing from a cleansing fluid through a selectively permeable integer, for example in a system such as a dialysis unit.
- The means for bleeding the offtake and/or recirculation tubes may then be provided in the form of a regulator, such as a simple valve or other control device for admitting or blocking the passage of irrigant and/or exudate through a bleed line branching from the recirculation path.
- 10 The means for fluid cleansing may as desired be a 'single-phase system'.

In this, the circulating fluid from the wound and the fluid reservoir passes through a self-contained system in which materials deleterious to wound healing are removed and the cleansed fluid, still containing materials that are beneficial in promoting wound healing, is returned via the recirculation tube to the wound bed. Such systems are described in further detail hereinafter in connection with the means for fluid cleansing.

Alternatively, where appropriate it may be provided in the form of a twophase system, such as a dialysis unit, or a biphasic liquid extraction unit.

In this, the circulating fluid from the wound and the fluid reservoir passes through a system in which the fluid recirculates in indirect or (less usually, direct) contact with a second fluid (dialysate) phase, more usually a liquid, in which materials deleterious to wound healing are removed and the cleansed fluid, still containing materials that are beneficial in promoting wound healing, is returned via the recirculation tube to the wound bed. Such systems are described in further detail hereinafter in connection with the means for fluid cleansing.

30

25

15

In use, typically, the means for flow switching between supply and recirculation tubes is set to admit fluid into the wound from the fluid reservoir but to close the wound to the fluid recirculation tube.

35 Then, any means for bleeding the offtake and/or recirculation tubes are is opened and the device for moving fluid through the wound and means for fluid cleansing is started.

32

The capacity of the apparatus flow path and the flow rate of irrigant and/or wound exudate from the wound will largely determine whether it is appropriate to run the device to prime the apparatus throughout the whole length of the apparatus flow path, i.e. to displace any existing fluid reservoir (often air) from the fluid recirculation path, and for how long it should be run. Typically, there is a preponderance of irrigant from the fluid reservoir over wound exudate in recirculation, so that use of the device for moving fluid through the wound is appropriate for this purpose.

10 It is allowed to run until the apparatus is primed throughout the whole length of the apparatus flow path.

Then, typically the means for bleeding the offtake and/or recirculation tubes is closed, and the means for flow switching between supply and recirculation tubes is set to close the wound to the fluid reservoir but to admit fluid into the wound from the fluid recirculation tube.

If the means for fluid cleansing is a two-phase system, such as a dialysis unit, or a biphasic extraction unit, the cleansing fluid is typically set in motion in contact with the surface of the selectively permeable integer, for example the polymer film, sheet or membrane. Of course, the cleansing fluid may less usually be static, and then this step is omitted.

As noted below in more detail, the volume of irrigant and/or wound exudate from the wound in recirculation may be increased by continuing addition to it of

a) wound exudate, and/or

5

15

20

30

35

b) fluid passing from a cleansing fluid through a selectively permeable integer, for example the polymer film, sheet or membrane of a two-phase system, such as a dialysis unit.

Additionally or alternatively, it may be desired to apply a negative pressure to the wound by means of a device for moving fluid through the wound and means for fluid cleansing applied to the fluid in recirculation in the fluid recirculation tube downstream of and away from the wound dressing.

In such case, it may be desirable to provide a system in which concomitant bleeding and/or recirculation is possible, and to make the necessary adjustments to maintain the desired balance of fluid in recirculation by means of the means for bleeding the offtake and/or recirculation tubes.

5

The volume of irrigant and/or wound exudate from the wound in recirculation may be decreased by continuing loss from it of fluid passing from a cleansing fluid through a selectively permeable integer, for example in a system such as a dialysis unit.

10

Additionally or alternatively, it may be desired to apply a positive pressure to the wound by means of a device for moving fluid through the wound and means for fluid cleansing applied to the fluid in recirculation in the fluid recirculation tube upstream of and towards the wound dressing.

15

The means for flow switching between supply and recirculation may be similarly provided in a form in which concomitant supply and/or recirculation is possible, and to make the necessary adjustments to maintain the desired balance of fluid in recirculation by means of the means for flow switching.

20

It will be appreciated that where a positive or negative pressure is to be applied to the wound, at least one hollow body in the recirculation flow path to and from the wound bed should have sufficient resilience against the pressure to allow any significant compression or decompression of the irrigant fluid to occur.

25

In all embodiments of the apparatus, the type and material of such bodies (which are defined by a film, sheet or membrane) that are described by way of example herein to be suitable for use in the present invention will be largely capable of this function.

30

35

Thus, examples of suitable materials for bodies defined by a film, sheet or membrane, such as inlet or offtake and/or recirculation tubes and structures such as bags, chambers and pouches, filled with irrigant fluid, e.g. the backing layer of the wound dressing are suitably elastically resilient thermoplastic materials that are potentially capable of this function when pressure is applied in this way.

WO 2005/105176

34

PCT/GB2005/001588

The present invention in this aspect provides several advantages.

One is that application of a positive pressure to the wound under the backing layer may make it possible to flood the tissue underlying the wound with one or more physiologically active components.

This may be effected in therapeutically active amounts, to promote greater wound healing than by treatment with the fluid physiologically active component(s) alone.

10

25

5

Such physiologically active components of the exudate that are beneficial to wound healing may be e.g. be enzymes or other species and may be supplied from the dialysate of a dialytic means for fluid cleansing.

15 It is believed that using the apparatus for aspirating, irrigating and/or cleansing wounds of the present invention cyclically the effects may be further enhanced.

Circulating wound fluid aids in movement of biological signalling molecules involved in wound healing to locations in the wound bed that are favourable to the wound healing process and/or to cells that would otherwise not be exposed to them, e.g. in a highly exuding wound.

This is especially the case in those embodiments of the apparatus of this first aspect of the present invention for aspirating, irrigating and/or cleansing wounds where there is an inlet or outlet manifold from which tubules radiate and run to the wound bed to end in openings that deliver and collect the fluid directly from the wound bed over an extended area.

30 Such materials include cytokines, enzymes, nutrients for wound cells to aid proliferation, oxygen, and other molecules that are beneficially involved in wound healing, such as growth factors, and others having beneficial effects (which may be further enhanced) in causing chemotaxis.

35 The whole length of the apparatus for aspirating, irrigating and/or cleansing wounds should be microbe-impermeable once the wound dressing is over the wound in use.

It is desirable that the wound dressing and the interior of the apparatus for aspirating, irrigating and/or cleansing wounds of the present invention is sterile.

The fluid may be sterilised in the fluid reservoir and/or the rest of the system in which the fluid recirculates, including the means for fluid cleansing, by ultraviolet, gamma or electron beam irradiation. This way, in particular reduces or eliminates contact of internal surfaces and the fluid with any sterilising agent.

10

15

20

25

30

Examples of other methods of sterilisation of the fluid also include e.g. the use of

ultrafiltration through microapertures or micropores, e.g. of 0.22 to 0.45 micron maximum cross-dimension, to be selectively impermeable to microbes; and

fluid antiseptics, such as solutions of chemicals, such as chlorhexidine and povidone iodine; metal ion sources, such as silver salts, e.g. silver nitrate; and hydrogen peroxide;

although the latter involve contact of internal surfaces and the fluid with the sterilising agent.

It may be desirable that the interior of the wound dressing, the rest of the system in which the fluid recirculates, and/or the wound bed, even for a wound in a highly exuding state, are kept sterile after the fluid is sterilised in the fluid reservoir, or that at least naturally occurring microbial growth is inhibited.

Thus, materials that are potentially or actually beneficial in this respect may be added to the irrigant initially, and as desired the amount in recirculation increased by continuing addition.

Examples of such materials include antibacterial agents (some of which are listed above), and antifungal agents.

35 Amongst those that are suitable are, for example triclosan, iodine, metronidazole, cetrimide, chlorhexidine acetate, sodium undecylenate, chlorhexidine and iodine.

36

Buffering agents, such as potassium dihydrogen phosphate/ disodium hydrogen phosphate. may be added to adjust the pH, as may local analgesics/anaesthetics, such as lidocaine/lignocaine hydrochloride, xylocaine (adrenoline, lidocaine) and/or anti-inflammatories, to reduce wound pain or inflammation or pain associated with the dressing.

It is also desirable to provide a system in which physiologically active components of the exudate that are beneficial to wound healing are not removed before or after the application of fluid cleansing, e.g. by the passive deposition of materials that are beneficial in promoting wound healing, such as proteins, e.g. growth factors.

This may occur at any point at least one inlet or outlet pipe through at least one aperture, hole, opening, orifice, slit or slot.

15

10

5

The fluid contained in the hollow body may the deposition of materials that are beneficial in promoting wound healing, and consequent coating.

- a) may be added to the irrigant initially, and as desired the amount in recirculation increased by continuing addition, or
- b) may be used at any point or on any integer in the recirculation path in direct contact with the fluid, e.g. on the means for fluid cleansing or any desired tube or pipe.

Examples of coating materials for surfaces over which the circulating fluid passes include

anticoagulants, such as heparin, and

high surface tension materials, such as PTFE, and polyamides,

which are useful for growth factors, enzymes and other proteins and derivatives.

30

The apparatus of the invention for aspirating, irrigating and/or cleansing wounds is provided with means for admitting fluids directly or indirectly to the wound under the wound dressing in the form of a fluid supply tube to a fluid reservoir.

37

PCT/GB2005/001588

The fluid reservoir may be of any conventional type, e.g. a tube, bag (such as a bag typically used for blood or blood products, e.g. plasma, or for infusion feeds, e.g. of nutrients), chamber, pouch or other structure, e.g. of polymer film, which can contain the irrigant fluid.

5

10

15

20

The reservoir may be made of a film, sheet or membrane, often with a (generally uniform) thickness similar to that of films or sheets used in conventional wound dressing backing layers, i.e. up to 100 micron, preferably up to 50 micron, more preferably up to 25 micron, and of 10 micron minimum thickness, and is often a resiliently flexible, e.g. elastomeric, and preferably soft, hollow body.

In all embodiments of the apparatus the type and material of the tubes throughout the apparatus of the invention for aspirating, irrigating and/or cleansing wounds and the fluid reservoir will be largely determined by their function.

To be suitable for use, in particular on chronic timescales, the material should be non-toxic and biocompatible, inert to any active components, as appropriate of the irrigant from the fluid reservoir and/or wound exudate in the apparatus flow path, and, in any use of a two-phase system dialysis unit, of the dialysate that moves into the circulating fluid in the apparatus.

When in contact with irrigant fluid, it should not allow any significant amounts of extractables to diffuse freely out of it in use of the apparatus.

It should be sterilisable by ultraviolet, gamma or electron beam irradiation and/or with fluid antiseptics, such as solutions of chemicals, fluid- and microbe-impermeable once in use, and flexible.

30

25

Examples of suitable materials for the fluid reservoir include synthetic polymeric materials, such as polyolefins, such as polyethylene, e.g. high-density polyethylene and polypropylene.

35 Suitable materials for the present purpose also include copolymers thereof, for example with vinyl acetate and mixtures thereof. Suitable materials for the present purpose further include medical grade poly(vinyl chloride).

Notwithstanding such polymeric materials, the fluid reservoir will often have a stiff area to resist any substantial play between it and components that are not mutually integral, such as the fluid supply tube towards the wound dressing, and may be stiffened, reinforced or otherwise strengthened, e.g. by a projecting boss.

The device for moving fluid through the wound and means for fluid cleansing may be any appropriate for this purpose, and may act at any appropriate point for this purpose.

10

5

It may apply a positive or negative pressure to the wound, although its prime purpose is to move fluid (irrigant from the fluid reservoir and/or wound exudate through the length of the apparatus flow path, rather than to apply a positive or negative pressure to the wound.

15

20

25

30

35

If applied to the fluid in recirculation in the fluid recirculation tube upstream of and towards the wound dressing and/or the fluid in the fluid supply tube towards the wound dressing (optionally or as necessary via means for flow switching between supply and recirculation), it will usually apply positive pressure (i.e. above-atmospheric pressure) to the wound bed.

Often the means for fluid cleansing is (most appropriately for its purpose) downstream of the wound dressing, and provides the highest resistance in the flow path. This is especially the case where the means for fluid cleansing is a single-phase system, e.g. with ultrafiltration through microapertures or micropores, thus enhancing applied positive pressure to the wound.

Where the device is applied to the fluid in recirculation in the fluid recirculation tube and/or the fluid in the fluid offtake tube downstream of and away from the wound dressing, it will usually apply negative pressure (i.e. below-atmospheric pressure or vacuum) to the wound bed.

Again, often the means for fluid cleansing is (most appropriately for its purpose) downstream of the wound dressing, and provides the highest resistance in the flow path, thus enhancing applied negative pressure to the wound.

39

The following types of pump may be used as desired:

reciprocating pumps, such as:

shuttle pumps - with an oscillating shuttle mechanism to move fluids at

rates from 2 to 50 ml per minute;

diaphragm pumps - where pulsations of one or two flexible diaphragms

displace liquid while check valves control the direction of

the fluid flow.

piston pumps - where pistons pump fluids through check valves, in

particular for positive and/or negative pressure on the

wound bed;

rotary pumps, such as:

15 centrifugal pumps

5

10

25

flexible impeller

pumps - where elastomeric impeller traps fluid between impeller

blades and a moulded housing that sweeps fluid through

the pump housing.

20 progressing cavity

pumps - with a cooperating screw rotor and stator, in particular

for higher-viscosity and particulate-filled exudate;

rotary vane pumps - with rotating vaned disk attached to a drive shaft

moving fluid without pulsation as it spins. The outlet can

be restricted without damaging the pump.

peristaltic pumps - with peripheral rollers on rotor arms acting on a flexible

fluid circulation tube to urge fluid current flow in the tube

in the direction of the rotor.

30 The type and/or capacity of the device will be largely determined by

a) the appropriate or desired fluid volume flow rate of irrigant and/or wound exudate from the wound, and

b) whether it is appropriate or desired to apply a positive or negative pressure to the wound bed, and the level of such pressure to the

35 wound bed

for optimum performance of the wound healing process, and by factors such as portability, power consumption and isolation from contamination.

Such a device may also suitably be one that is capable of pulsed, continuous, variable, reversible and/or automated and/or programmable fluid movement. It may in particular be a pump of any of these types.

In practice, even from a wound in a highly exuding state, such a rate of exudate flow is only of the order of up to 75 microlitres / cm²/ hr (where cm² refers to the wound area).

The fluid can be highly mobile (owing to the proteases present). Exudate levels drop and consistency changes as the wound heals, e.g. to a level for the same wound that equates to 12.5 – 25 microlitres / cm²/ hr.

Where materials deleterious to wound healing are removed by a two-phase system (see below.), such as a dialysis unit, fluid is also potentially lost to the system through the means for fluid cleansing.

This may occur, e.g. through a dialysis polymer film, sheet or membrane which is also permeable to water, in addition to materials deleterious to wound healing.

20

35

15

The balance of fluid in recirculation may thus further decrease, but may be adjusted to minimise this undesired loss in a routine manner as described hereinbefore.

Hence, it will be seen that the circulating fluid from the wound will typically contain a preponderance of irrigant over wound exudate in recirculation from the fluid reservoir.

The type and/or capacity of the device will thus be largely determined in this respect by the appropriate or desired fluid volume flow rate of irrigant, rather than that of exudate, from the wound.

In practice, such a rate of flow of total irrigant and/or wound exudate will be of the order of 1 to 1000, e.g. 3 to 300, and less preferably 1 to 10 ml / cm² / 24 hour, where the cm² refers to the wound area.

The volume of irrigant and/or wound exudate in recirculation may vary over a wide range, but will typically be e.g. 1 to 8 l. (for example for large torso wounds), 200 to 1500 ml (for example for axillary and inguinal wounds), and 0.3 to 300 ml for limb wounds when the therapy is applied in this way.

5

20

25

35

In practice, suitable pressures are of the order of up to 25% atm such as up to 10% atm. positive or negative pressure on the wound bed, the apparatus being operated as a closed recirculating system.

The higher end of these ranges are potentially more suitable for hospital use, where relatively high % pressures and/or vacua may be used safely under professional supervision.

The lower end is potentially more suitable for home use, where relatively high % pressures and/or vacua cannot be used safely without professional supervision, or for field hospital use.

The device may be a peristaltic pump or diaphragm pump, e.g. preferably a small portable diaphragm or peristaltic pump. These are preferred types of pump, in order in particular to reduce or eliminate contact of internal surfaces and moving parts of the pump with (chronic) wound exudate, and for ease of cleaning.

It may suitably be one that applies positive pressure to the wound and/or the means for fluid cleansing. A preferred pump when the applied pressure is positive is a peristaltic pump, e.g. a small, portable peristaltic pump, mounted upstream of the means for fluid cleansing.

Where the pump is a peristaltic pump, this may be e.g. an Instech Model P720 miniature peristaltic pump, with a flow rate: of 0.2 – 180ml/hr and a weight of < 0.5 Kg. This is potentially useful for home and field hospital use.

The pump may suitably be one that applies negative pressure to the wound and/or the means for fluid cleansing. A preferred pump when the applied pressure is negative is a diaphragm pump, e.g. a small, portable diaphragm pump, mounted downstream of the dressing or the means for fluid cleansing.

42

Where the pump is a diaphragm pump, and preferably a small portable diaphragm pump, the one or two flexible diaphragms that displace liquid may each be, for example a polymer film, sheet or membrane. These may be used to create pulsations in the fluid flow.

5

They may be provided by any other device that is convenient, inter alia an electromechanical oscillator, a core of a solenoid or a ferromagnetic integer and coil in which the direction of current flow alternates, a rotary cam and follower, and so on.

10

The outlet from the dressing passes to the means for fluid cleansing for removal of materials deleterious to wound healing from wound exudate, and in turn to the fluid recirculation tube(s).

- The apparatus of the invention for aspirating, irrigating and/or cleansing wounds is provided with means for fluid cleansing, which may be
 - a) a single-phase system, such as an ultrafiltration unit, or a chemical absorption and/or adsorption unit; or
- b) a two-phase system, such as a dialysis unit, or a biphasic extraction unit.

In the former, circulating fluid from the wound and the fluid reservoir passes through a self-contained system in which materials deleterious to wound healing are removed and the cleansed fluid, still containing materials that are beneficial in promoting wound healing are returned to the wound.

The single-phase system may be of any conventional type.

Examples of the means for fluid cleansing in such a system include a macroor microfiltration unit, which appropriately comprises one or more macroscopic and/or microscopic filters.

These are to retain particulates, e.g. cell debris and micro-organisms, allowing proteins and nutrients to pass through.

25

30

Alternatively, they also include an ultrafiltration unit, such as a one in which the cleansing integer is a filter for materials deleterious to wound healing, for example a high throughput, low protein-binding polymer film, sheet or membrane. This is selectively impermeable to materials deleterious to wound healing, which are removed and the cleansed fluid, still containing materials that are beneficial in promoting wound healing is passed by it.

The membrane may preferably be of a hydrophilic polymeric material, such as a cellulose acetate – nitrate mixture, polyvinylidene chloride, and, for example hydrophilic polyurethane.

Examples of less preferred materials include hydrophobic materials also including polyesters, such as polycarbonates, PTFE, and polyamides, e.g. 6-6 and 6 - 10, and hydrophobic polyurethanes, and quartz and glass fibre.

15

10

5

It has microapertures or micropores, the maximum cross-dimension of which will largely depend on the species that are to be selectively removed in this way and those to which it is to be permeable.

- The former may be removed with microapertures or micropores, e.g. typically with a maximum cross-dimension in the range of 20 to 700 micron, e.g. 20 to 50 nm (for example for undesired proteins), 50 to 100 nm, 100 to 250 nm, 250 to 500 nm and 500 to 700 nm.
- The filter integer may be a flat sheet or a membrane of a polymeric material in a more convoluted form, e.g. in the form of elongate structure, such as pipes, tubules, etc.
- The system may be a chemical adsorption unit, for example one in which a particulate, such as a zeolite, or a layer, e.g. of a functionalised polymer has sites on its surface that are capable of removing materials deleterious to wound healing on passing the circulating fluid from the wound and the fluid reservoir over them.
- The materials may be removed, e.g. by destroying or binding the materials that are deleterious to wound healing, by, for example chelators and/or ion exchangers, degraders, which may be enzymes.

44

Examples of such also include less specific chemical adsorption units, for example one in which a physical absorbent, such as activated carbon or a zeolite, has non-specific sites on its surface that are capable of removing materials deleterious to wound healing on passing the circulating fluid from the wound and the fluid reservoir over them.

The cleansing integer, for example the polymer film, sheet or other chemical absorption and/or adsorption means, etc should of course be capable of removing materials deleterious to wound healing at a practical rate for a given capacity of the apparatus flow path and the flow rate of irrigant.

In the two-phase system, circulating fluid from the wound and the fluid reservoir in indirect or (less usually, direct) contact with a second fluid (dialysate) phase, more usually a liquid.

15

20

30

35

10

5

Thus, in one form, a biphasic liquid extraction unit, the second fluid phase is (usually) a liquid that is immiscible with the circulating fluid from the dressing, over a surface of which the circulating fluid passes in direct contact with the cleansing fluid. Materials deleterious to wound healing are removed into the dialysate, and the cleansed fluid, still containing materials that are beneficial in promoting wound healing, is returned via the recirculation tube to the wound bed.

Examples of such means for fluid cleansing include those wherein the second fluid (dialysate) phase is perfluorodecalin and like materials

Alternatively, where appropriate it may be provided in a form in which the two fluids (recirculation fluid and dialysate) are separated by a significantly two-dimensional integer, for example a polymer film, sheet or membrane or hollow fibre or filament that is permeable to materials in the circulating fluid in the apparatus.

Again, materials deleterious to wound healing are removed into the dialysate, and the cleansed fluid, still containing materials that are beneficial in promoting wound healing, is returned via the recirculation tube to the wound bed.

In either form in which the two-phase system, such as a dialysis unit, is provided, in use typically the dialysate moves past the circulating fluid in the apparatus in a co- or preferably counter-current direction.

5 Pumps, such as peristaltic pumps, and/or valves control the direction of the two fluid flows.

However, the cleansing fluid may less usually be static, although this may not provide a system with sufficient (dynamic) surface area to remove materials deleterious to wound healing from wound exudate at a practical rate.

Typical dialysate flow rates in a dialytic means for fluid cleansing in the present apparatus for aspirating, irrigating and/or cleansing wounds are those used in the conventional type of two-phase system, such as a dialysis unit for systemic therapy.

The integer may be a film, sheet or membrane, often of the same type, and of the same (generally uniform) thickness, as those used in conventional two-phase system, such as a dialysis unit for systemic therapy.

20

30

10

15

The film, sheet or membrane may be substantially flat, and depending on any pressure differential across it may require other materials on or in it to stiffen, reinforce or otherwise strengthen it.

However, this may not provide a system with sufficient functional surface area to remove materials deleterious to wound healing from wound exudate at a practical rate.

To be suitable for use, in particular in chronic wound dialysis, with relatively high concentrations of materials that are deleterious to wound healing, it may be advantageous to provide a system in which the film, sheet or membrane of a polymeric material is in a more convoluted form.

This may be in the form of elongate structures, such as pipes, tubes hollow fibres or filaments or tubules of a round cross-section, e.g. elliptical or circular, e.g. in a parallel array with spaces therebetween.

46

The wound irrigant and/or wound exudate may recirculate through the inside and the cleansing fluid may pass into the spaces between adjacent pipes, tubes or tubules in a co- or preferably counter-current direction, or vice versa.

- Again, materials deleterious to wound healing are removed into the dialysate, and the cleansed fluid, still containing materials that are beneficial in promoting wound healing, is returned via the recirculation tube to the wound.
- Where the means for fluid cleansing is a two-phase system, e.g. in the form of a dialysis unit, or a biphasic extraction unit, the circulating fluid from the wound and the fluid reservoir passes across one surfaces of a significantly two-dimensional integer, for example a polymer film, sheet or membrane which is selectively permeable to materials deleterious to wound healing.
- These are removed by passing a cleansing fluid across the other surface of the integer. The integer may be a film, sheet or membrane that is selectively permeable to the foregoing materials deleterious to wound healing.
 - Examples of these as above include
- oxidants, such as free radicals, e.g. peroxide and superoxide; iron II and iron III; all involved in oxidative stress on the wound bed;
 - proteases, such as serine proteases, e.g. elastase and thrombin; cysteine proteases; matrix metalloproteases, e.g. collagenase; and carboxyl (acid) proteases;
- endotoxins, such as lipopolysaccharides;
 - bacterial autoinducer signalling molecules, such as homoserine lactone derivatives, e.g. oxo-alkyl derivatives;
 - inhibitors of angiogenesis such as thrombospondin-1 (TSP-1), plasminogen activator inhibitor, or angiostatin (plasminogen fragment);
- pro-inflammatory cytokines such as tumour necrosis factor alpha (TNF α) and interleukin 1 beta (IL-1 β),

and

inflammatories, such as lipopolysaccharides, and e.g. histamine.

47

PCT/GB2005/001588

Examples of suitable materials for the film, sheet or membrane (typically in the form of conformable hollow bodies defined by the film, sheet or membrane, such as the structures described hereinbefore) include natural and synthetic polymeric materials.

5

The membrane may be of one or more hydrophilic polymeric materials, such as a cellulose derivative, e.g. regenerated cellulose, a cellulose mono-, di- or tri- esters, such as cellulose mono-, di- or tri-acetate, benzyl cellulose and Hemophan, and mixtures thereof.

10

Examples of other materials include hydrophobic materials, such as aromatic polysulphones, polyethersulphones, polyetherether-sulphones, polyetherether, polyetherether, and sulphonated derivatives thereof, and mixtures thereof.

15

Examples of other materials include hydrophobic materials, such as polyesters, such as polycarbonates and polyamides, e.g. nylon 6 - 6 and 6 - 10 polyamide; polyacrylates, including, e.g. poly(methyl methacrylate), polyacrylonitrile and copolymers thereof, for example acrylonitrile - sodium metallosulphonate copolymers; and poly(vinylidene chloride).

20

Suitable materials for the present membranes include thermoplastic polyolefins, such as polyethylene e.g. high-density polyethylene, polypropylene, copolymers thereof, for example with vinyl acetate and polyvinyl alcohol, and mixtures thereof.

30

25

The dialysis membrane should have a molecular weight cut off (MWCO) chosen to allow selective perfusion of species deleterious to wound healing that have been targeted for removal from the wound. For example, perfusion of the serine protease elastase (molecular weight 25900 Dalton) would require a membrane with MWCO >25900 Dalton. The MWCO threshold can be varied to suit each application between 1 and 3000000 Dalton.

35

Preferably, the MWCO should be as close as possible to this weight to exclude interference by larger competitor species.

PCT/GB2005/001588

For example, such a membrane with MWCO >25900 Dalton does not allow any significant amounts of the antagonist to elastase, alpha-1-antitrypsin (AAT) (molecular weight 54000 Dalton), which occurs naturally in wounds, to diffuse freely out of the wound fluid into the dialysate.

5

20

25

35

The inhibitor, which is beneficial in promoting chronic wound healing, remains in contact with the wound bed, and can act beneficially on it, whilst the elastase that is deleterious to wound healing is removed.

10 Such use of the present apparatus is, e.g. favourable to the wound healing process in chronic wounds, such as diabetic foot ulcers, and especially decubitus pressure ulcers.

As noted hereinafter, antagonists, for example degrading enzymes, or sequestrating agents for elastase on the dialysate side of the membrane, may be used to enhance the removal of this protease from wound exudate.

Where it is desired to remove several different materials that are deleterious to wound healing, it may be advantageous to provide a system of modules in series, each of which removes a different material. This allows incompatible cleansing materials to be used on the same fluid and/or wound exudates.

Preferably any such system is a conventional automated, programmable system which can cleanse the wound irrigant and/or wound exudate with minimal supervision.

As noted above in more detail, fluid passes from a cleansing fluid through a selectively permeable integer.

This may be the typical permeable polymer film, sheet or membrane of a twophase system, such as a dialysis unit.

Additionally, solutes or disperse phase species will pass from the dialysate into the irrigant and/or wound exudate through the dialysis polymer film, sheet or membrane.

This property may be used to perfuse materials beneficial to wound healing into the irrigant and/or exudate from a dialysate.

In this less conventional type of infusion feed, a broad spectrum of species will usually pass into the exudate and/or irrigant fluid from the dialysate.

These include

25

30

35

ionic species, such as bicarbonate;

vitamins, such as ascorbic acid (vitamin C) and vitamin E, and stable derivatives thereof, and mixtures thereof; to relieve oxidative stress on the wound bed;

pH buffering agents, such as potassium dihydrogen phosphate/ disodium hydrogen phosphate,

local analgesics/anaesthetics, such as lidocaine/lignocaine hydrochloride and xylocaine (adrenoline lidocaine) and/or anti-inflammatories, to reduce wound pain or inflammation or pain associated with the dressing

nutrients to aid proliferation of wound cells, such as amino acids, sugars, low molecular weight tissue building blocks and trace elements; and other cell culture medium species; and

20 gases, such as air, nitrogen, oxygen and/or nitric oxide.

For the purposes of fluid cleansing in the apparatus of the present invention, both the single-phase system, such as an ultrafiltration unit, and two-phase system, such as a dialysis unit, may have captive (non-labile, insoluble and/or immobilised) species such as the following, bound to an insoluble and/or immobilised) substrate over and/or through which the irrigant and/or wound exudate from, the wound dressing passes in turn to the fluid recirculation tube(s):

antioxidants and free radical scavengers, such as 3-hydroxytyramine (dopamine), ascorbic acid (vitamin C), vitamin E and glutathione, and stable derivatives thereof, and mixtures thereof; to relieve oxidative stress on the wound bed;

metal ion chelators and/or ion exchangers, such as transition metal ion chelators, such as iron III chelators (Fe III is involved in oxidative stress on the wound bed.), such as desferrioxamine (DFO), 3-hydroxytyramine (dopamine): iron III reductants;

5

30

protease inhibitors, such as TIMPs and alpha 1-antitrypsin (AAT); serine protease inhibitors, such as 4-(2-aminoethyl)-benzene sulphonyl fluoride (AEBSF, PefaBloc) and N α -p-tosyl-L-lysine chloro-methyl ketone (TLCK) and ϵ -aminocaproyl-p-chlorobenzylamide; cysteine protease inhibitors; matrix metalloprotease inhibitors; and carboxyl (acid) protease inhibitors; sacrificial redox materials that are potentially or actually beneficial in promoting wound healing, by the removal of materials that trigger the expression into wound exudate of redox-sensitive genes that are deleterious to wound healing:

10 autoinducer signalling molecule degraders, which may be enzymes; and anti-inflammatory materials to bind or destroy lipopolysaccharides, e.g. peptidomimetics

Other physiologically active components of the exudate that are deleterious to wound healing may be removed in this way.

These may be removed with suitable chelators and/or ion exchangers, degraders, which may be enzymes, or other species.

- The following types of functionalised substrate has sites on its surface that are capable of removing materials deleterious to wound healing on passing the circulating fluid from the wound and the fluid reservoir over them: heterogeneous resins, for example silica-supported reagents such as: metal scavengers,
- 3-(diethylenetriamino)propyl-functionalised silica gel
 2-(4-(ethylenediamino)benzene)ethyl-functionalised silica gel
 3-(mercapto)propyl-functionalised silica gel
 - 3-(1-thioureido)propyl-functionalised silica gel triamine tetraacetate-functionalised silica gel

or electrophilic scavengers,

4-carboxybutyl-functionalised silica gel

4-ethyl benzenesulfonyl chloride-functionalised silica gel propionyl chloride-functionalised silica gel

- 35 3-(isocyano)propyl-functionalised silica gel
 - 3-(thiocyano)propyl-functionalised silica gel
 - 3-(2-succinic anhydride)propyl-functionalised silica gel

3-(maleimido)propyl-functionalised silica gel

- or nucleophilic scavengers,
- 3-aminopropyl-functionalised silica gel
- 5 3-(ethylenediamino)-functionalised silica gel
 - 2-(4-(ethylenediamino)propyl-functionalised silica gel
 - 3-(diethylenetriamino)propyl-functionalised silica gel
 - 4-ethyl-benzenesulfonamide-functionalised silica gel
 - 2-(4-toluenesulfonyl hydrazino)ethyl-functionalised silica gel
- 10 3-(mercapto)propyl-functionalised silica gel

dimethylsiloxy-functionalised silica gel

- or base or acid scavengers,
- 3-(dimethylamino)propyl-functionalised silica gel
- $3-(1,3,4,6,7,8-hexahydro-2H-pyrimido-[1,2-\alpha]pyrimidino)$ propyl-functionalised
- 15 silica gel
 - 3-(1-imidazol-1-yl)propyl-functionalised silica gel
 - 3-(1-morpholino)propyl-functionalised silica gel
 - 3-(1-piperazino)propyl-functionalised silica gel
 - 3-(1-piperidino)propyl-functionalised silica gel
- 20 3-(4,4'-trimethyldipiperidino)propyl-functionalised silica gel
 - 2-(2-pyridyl)ethyl-functionalised silica gel
 - 3-(trimethylammonium)propyl-functionalised silica gel

or the reagents,

- 25 3-(1-cyclohexylcarbodiimido)propyl-functionalised silica gel
 - TEMPO-functionalised silica gel
 - 2-(diphenylphosphino)ethyl-functionalised silica gel
 - 2-(3,4-cyclohexyldiol)propyl-functionalised silica gel
 - 3-(glycidoxy)propyl-functionalised silica gel
- 30 2-(3,4-epoxycyclohexyl)propyl-functionalised silica gel
 - 1-(allyl)methyl-functionalised silica gel
 - 4-bromopropyl-functionalised silica gel
 - 4-bromophenyl-functionalised silica gel
 - 3-chloropropyl-functionalised silica gel
- 35 4-benzyl chloride-functionalised silica gel
 - 2-(carbomethoxy)propyl-functionalised silica gel
 - 3-(4-nitrobenzamido)propyl-functionalised silica gel

3-(ureido)propyl-functionalised silica gel

or any combinations of the above.

The use of such captive (non-labile, insoluble and/or immobilised) species, such as the foregoing, bound to an insoluble and immobilised) substrate over and/or through which the irrigant and/or wound exudate from, the wound dressing passes has been described hereinbefore as suitable for the means for fluid cleansing.

10

However, they may additionally, where appropriate, be used in any part of the apparatus that is in contact with the irrigant and/or wound exudate, but often within the dressing, for removal of materials deleterious to wound healing from wound.

15

A backing layer in the wound dressing with ribs or ridges may be used to assist in channelling fluid across a larger area over a longer dwell time, and hence improve the cleansing of the irrigant in the wound dressing.

The means for fluid cleansing may additionally, where appropriate, comprise one or more macroscopic and/or microscopic filters.

These are to retain particulates, e.g. cell debris and micro-organisms, allowing proteins and nutrients to pass through.

Alternatively, a less conventional type of two-phase system (see above), such as a dialysis unit, may be used as the means for fluid cleansing. In this type, the dialysis polymer film, sheet or membrane is not an integer selectively permeable to materials deleterious to wound healing, such as proteases, such as serine proteases, e.g. elastase and thrombin; cysteine protease; matrix metalloproteases, e.g. collagenase; and carboxyl (acid) proteases;

endotoxins, such as lipopolysaccharides;

inhibitors of angiogenesis such as thrombospondin-1 (TSP-1), plasminogen activator inhibitor, or angiostatin (plasminogen fragment);

pro-inflammatory cytokines such as tumour necrosis factor alpha (TNF α) and interleukin 1 beta (IL-1 β); and

53

oxidants, such as free radicals, e.g., e.g. peroxide and superoxide; and metal ions, e.g. iron II and iron III; all involved in oxidative stress on the wound bed.

It will however also permit components of the exudate from a wound and/or irrigant fluid that may be larger or smaller molecules, but are beneficially involved in wound healing to pass into and through it.

In the dialysate, or preferably in one or more solid structural integers with at least one surface in contact with the dialysate, in the means for fluid 10 cleansing, there are one or more materials that can remove materials deleterious to wound healing from wound exudate, by being antagonists to such species, for example enzymes or others, such as protease inhibitors, such as serine protease inhibitors, such as 4-(2-15 aminoethyl)-benzene sulphonyl fluoride (AEBSF, PefaBloc) and Nα-p-tosyl-L-lysine chloromethyl ketone (TLCK) and ε-aminocaprovl-pchlorobenzylamide; cysteine protease inhibitors; matrix metalloprotease inhibitors; and carboxyl (acid) protease inhibitors; binders and/or degraders, such as anti-inflammatory materials to bind or 20 destroy lipopolysaccharides, e.g. peptidomimetics; anti-oxidants, such as 3-hydroxytyramine (dopamine), ascorbic acid (vitamin C), vitamin E and glutathione, and stable derivatives thereof, and mixtures

chelators and/or ion exchanges, such as desferrioxamine (DFO), 3-25 hydroxytyramine (dopamine),

thereof; to relieve oxidative stress on the wound bed; and

30

They further include peptides (including cytokines, e.g. bacterial cytokines, such as α -amino- γ -butyrolactone and L-homocarnosine); and sacrificial redox materials that are potentially or actually beneficial in promoting wound healing, such as iron III reductants; and/or regeneratable materials of this type, such as glutathione redox systems; and other physiologically active components.

In use of the two-phase system dialysis unit, of this less conventional type, a broad spectrum of species will usually pass into the dialysate from the exudate.

Some (mainly ionic) species will pass from the dialysate into the irrigant and/or wound exudate through the dialysis polymer film, sheet or membrane that is not very selectively permeable to materials deleterious to wound healing.

5

25

30

35

The components of the exudate from a wound and/or irrigant fluid will diffuse freely to and fro through it.

If (preferably) none of the dialysate is voided to waste, e.g. to a collection bag, a steady state concentration equilibrium is eventually set up between the dialysate and the irrigant and/or wound exudate, which is 'topped up' from the wound dressing.

Circulating wound fluid aids in the quicker attainment of this equilibrium of materials beneficial in promoting wound healing.

It also returns them to the site where they can be potentially of most benefit, i.e. the wound bed.

The target materials deleterious to wound healing also pass into the dialysate from the exudate through the dialysis polymer film, sheet or membrane that is not very selectively permeable to materials deleterious to wound healing.

Unlike the other components of the exudate from a wound and/or irrigant fluid, the target materials deleterious to wound healing come into contact with the dialysate, or preferably with one or more solid structural integers with at least one surface in the dialysate, and are removed by the appropriate antagonists, binders and/or degraders,

chelators and/or ion exchangers and redox agents, etc. The cleansed fluid, still containing some materials that are beneficial in promoting wound healing, is returned to the recirculation tube.

Unlike the other components of the exudate from a wound and/or irrigant fluid the target materials are constantly removed from the dialysate, very little of these species will pass from the dialysate into the irrigant and/or wound exudate, and a steady state concentration equilibrium is not set up, even if the species are constantly 'topped up' from the wound dressing.

It is believed that circulating wound fluid aids in removal from recirculation of the materials deleterious to wound healing from wound exudate, whilst retaining materials that are beneficial in promoting wound healing in contact with the wound.

5

10

15

25

30

35

A particular advantage of this form of the two-phase system, is that where a material that can remove materials deleterious to wound healing from wound exudate is (cyto)toxic or bioincompatible, or not inert to any components that are beneficial in promoting wound healing, the system does not allow any significant amounts of antagonist to diffuse freely out of the dialysate into the irrigant fluid. The active material can act beneficially on the fluid however.

The film sheet or membrane is preferably a dialysis membrane of molecular weight cut off (MWCO) (as conventionally defined) chosen to allow perfusion of species targeted for sequestration or destruction.

For example, sequestration of the serine protease elastase (molecular weight 25900 Dalton) would require a membrane with MWCO >25900 Dalton.

The MWCO threshold can be varied to suit each application between 1 and 3000000 Dalton. Preferably, the MWCO should be as close as possible to this weight to exclude sequestering interference by larger competitor species.

Both the single-phase system, such as an ultrafiltration unit, and two-phase system, such as a dialysis unit, may be in modular form that is relatively easily demountable from the apparatus of the invention. The system may suitably comprise one or more such modules.

The conduits through which respectively

- a) the irrigant and/or wound exudate passes from the wound dressing and
- b) the cleansed fluid, still containing materials that are beneficial in promoting wound healing, is returned to the recirculation tube, and
- c) (in the case where the means is provided in the form of a two-phase system, such as an dialysis unit) through which the cleansing fluid enters and exits the means

preferably have means for, on module disconnection and withdrawal,

i) switching off the flow and

56

ii) providing an immediate fluid-tight seal or closure over the ends of the conduits and the cooperating tubes in the rest of the apparatus of the invention so exposed.

to prevent continuing passage of irrigant and/or exudate and cleansed fluid, and cleansing fluid.

The apparatus of the invention for aspirating, irrigating and/or cleansing wounds is provided with means for bleeding the offtake and/or recirculation tubes, such as a regulator, such as a valve or other control device for bleeding fluids from the wound.

The device for moving fluid through the wound and means for fluid cleansing is used to move irrigant to the wound dressing and apply the desired positive or negative pressure on the wound bed.

15

10

5

The desired balance of fluid in recirculation tube will typically be regulated by means of

- a) the means for bleeding the offtake and/or recirculation tubes.
- b) the means for flow switching between supply and recirculation, and/or
- 20 c) the means for moving fluid over the wound bed and through the means for fluid cleansing,

as appropriate.

Thus, e.g. if

- 25 a) the apparatus for aspirating, irrigating and/or cleansing wounds is a single-phase system, such as an ultrafiltration unit.
 - b) the wound is not in a highly exuding state and
 - c) it is not appropriate or desired to admit fluid into the wound from the fluid reservoir.
- there is no or negligible change in the balance of fluid in recirculation.

Once it has been primed throughout, e.g. to the desired positive or negative pressure on the wound bed, the apparatus may be operated as a closed recirculating system.

57

PCT/GB2005/001588

The means for flow switching between supply and recirculation tubes is set to close the wound to the fluid reservoir via the fluid supply tube, and the means for bleeding the offtake and/or recirculation tubes are also closed.

5 If

10

15

20

- a) the apparatus for aspirating, irrigating and/or cleansing wounds is a single-phase system, such as an ultrafiltration unit.
- b) the wound is in a highly exuding state and/or
- c) it is appropriate or desired to admit fluid into the wound from the fluid reservoir,

there is a positive change in the balance of fluid in recirculation.

Once it has been primed throughout, e.g. to the desired positive or negative pressure on the wound bed, the apparatus cannot be operated as a closed recirculating system, without the pressure to the wound bed increasing, possibly undesirably.

The means for bleeding the offtake and/or recirculation tubes must be opened to some extent to relieve positive pressure on the wound bed. The bleed-off may be voided to waste, e.g. to a collection bag.

Materials that are beneficial in promoting wound healing may be lost to the site where they can be potentially of most benefit, i.e. the wound bed, when the therapy is applied in this way.

25

30

35

However, the balance of fluid in recirculation may be routinely adjusted to minimise this undesired loss.

The factors that determine the balance of fluid in recirculation in an apparatus with a two-phase system means for fluid cleansing in the form of a dialysis unit, or a biphasic extraction unit have been described hereinbefore in detail hereinbefore in connection with the operation of the apparatus. It is sufficient to note here that at some point after steady state recirculation established through the length of the apparatus flow path, it may be necessary that any bleed valve is opened, if overall the fluid level is increasing by transfer from the dialysate to an undesirable extent.

Other combinations, and the necessary adjustments to maintain the desired balance of fluid in recirculation tube by means of

- a) the means for bleeding the offtake and/or recirculation tubes,
- b) the means for flow switching between supply and recirculation, and/or
- 5 c) the means for moving fluid will be apparent to the skilled person.

15

25

30

The outlet from the means for bleeding the offtake and/or recirculation tubes may be collected and monitored and used to diagnose the status of the wound and/or its exudate.

The waste reservoir may be of any conventional type, e.g. a tube, bag (such as a bag typically used as an ostomy bag), chamber, pouch or other structure, e.g. of polymer film, which can contain the irrigant fluid that has been bled off. In all embodiments of the apparatus, the type and material of the waste reservoir will be largely determined by its function. To be suitable for use, the material need only be fluid-impermeable once in use, and flexible.

20 Examples of suitable materials for the fluid reservoir include synthetic polymeric materials, such as polyolefins, such as poly (vinylidene chloride).

Suitable materials for the present purpose also include polyethylene, e.g. high-density polyethylene, polypropylene, copolymers thereof, for example with vinyl acetate and mixtures thereof.

In a second aspect of the present invention there is provided a conformable wound dressing, characterised in that it comprises a backing layer with a wound-facing face which is capable of forming a relatively fluid-tight seal or closure over a wound and has

- at least one inlet pipe for connection to a fluid supply tube, which passes through and/or under the wound-facing face, and
- at least one outlet pipe for connection to a fluid offtake tube, which passes through and/or under the wound-facing face,
- the point at which the or each inlet pipe and the or each outlet pipe passes through and/or under the wound-facing face forming a relatively fluid-tight seal or closure over the wound; and

means for applying flow stress to the wound bed.

The dressing is advantageously provided for use in a bacteria-proof pouch.

5 Examples of suitable forms of such wound dressings are as described by way of example hereinbefore.

In a third aspect of the present invention there is provided a method of treating wounds to promote wound healing using the apparatus for aspirating, irrigating and/or cleansing wounds of the present invention.

10

35

The present invention will now be described by way of example only with reference to the accompanying drawings in which:

Figure 1 is a schematic view of an apparatus for aspirating, irrigating and/or cleansing a wound according to the first aspect of the present invention.

It has a single-phase system means for fluid cleansing in the form of an ultrafiltration unit.

The dressing in the apparatus is that shown in Figure 8 (27), i.e. a form for deeper wounds that comprises an inlet manifold in the form of a deeply indented disc much like a multiple Maltese cross or a stylised rose, provided with pores or microapertures that deliver the circulating fluid directly towards the wound bed via the apertures. It is shown schematically with the detail of the inlet manifold omitted for clarity.

Figure 2 is a schematic view of an apparatus for aspirating, irrigating and/or cleansing a wound according to the first aspect of the present invention.

It has a two-phase system means for fluid cleansing in the form of a dialysis unit, or a biphasic extraction unit.

Figures 3 to 8 (27) are cross-sectional views of conformable wound dressings, of the second aspect of the present invention for aspirating and/or irrigating wounds.

In these, Figures 3a and 4a are plan views of the wound dressings, and Figures 3b and 4b are cross-sectional side views of the wound dressings.

Figures 5 to 7 are cross-sectional side views of the wound dressings.

5

Figure 9 (11) is a schematic view of an apparatus for aspirating, irrigating and/or cleansing a wound according to the first aspect of the present invention. It has a single-phase system means for fluid cleansing in the form of an ultrafiltration unit.

10

Figure 10 (12) is a schematic view of an apparatus for aspirating, irrigating and/or cleansing a wound according to the first aspect of the present invention. It has a two-phase system means for fluid cleansing in the form of a dialysis unit, or a biphasic extraction unit.

15

25

30

35

Referring to Figure 1, the apparatus (1) for aspirating, irrigating and/or cleansing wounds comprises

a conformable wound dressing (2), having

a backing layer (3) which is capable of forming a relatively fluid-tight seal or closure (4) over a wound (5) and

one inlet pipe (6) for connection to a fluid supply tube (7), which passes through the wound-facing face of the backing layer (3) at (8), and

one outlet pipe (9) for connection to a fluid offtake tube (10), which passes through the wound-facing face at (11),

the points (8), (11) at which the inlet pipe and the outlet pipe passes through and/or under the wound-facing face forming a relatively fluid-tight seal or closure over the wound,

the inlet pipe being connected via means for flow switching between supply and recirculation, here a T- valve (14), by the fluid supply tube (7) to a fluid reservoir (12) and to a fluid recirculation tube (13) having a means for bleeding the tube, here a bleed T-valve (16) to waste, e.g. to a collection bag (not shown),

the outlet pipe (9) being connected to a fluid offtake tube (10), connected in turn to

means for fluid cleansing (17), here in the form of an ultrafiltration unit, connected to the inlet pipe (6) via the fluid recirculation tube (13) and T- valve (14), and

a device for moving fluid through the wound and means for fluid cleansing (17), here a peristaltic pump (18), e.g. preferably a small portable peristaltic pump, acting on the fluid circulation tube (13) with the peripheral rollers on its rotor (not shown) to apply a low negative pressure on the wound.

The ultrafiltration unit (17) is a single-phase system.

10

15

20

5

In this the circulating fluid from the wound and the fluid reservoir passes through a self-contained system in which materials deleterious to wound healing are removed and the cleansed fluid, still containing materials that are beneficial in promoting wound healing, is returned via the recirculation tube to the wound bed.

(In a variant of this apparatus, there are two inlet pipes (6), which are connected respectively to a fluid supply tube (7) and fluid recirculation tube (13), respectively having a first valve (19) for admitting fluid into the wound from the fluid reservoir (12) and a second valve (20) for admitting fluid into the wound from the recirculation tube.

Usually in use of the apparatus, when the first valve (19) is open, the second valve (20) is shut, and vice versa.)

25

30

In use of the apparatus (1), the valve (16) is opened to a collection bag (not shown), and the T- valve (14) is turned to admit fluid from the fluid reservoir to the wound dressing through the fluid supply tube (7) and inlet pipe (6). (In the variant of this apparatus having two inlet pipes (6), which are connected respectively to a fluid supply tube (7) and fluid recirculation tube (13), the first valve (19) for admitting fluid into the wound from the fluid reservoir (12) is opened and the second valve (20) is shut, and vice versa.)

The pump (18) is started to nip the fluid recirculation tube (13) with the peripheral rollers on its rotor (not shown) to apply a low negative pressure on the wound.

It is allowed to run until the apparatus is primed throughout the whole length of the apparatus flow path and excess fluid is voided to waste via the bleed T-valve (16) into the collection bag (not shown).

The T-valve (14) is then turned to switch from supply and recirculation, i.e. is set to close the wound to the fluid reservoir (12) but to admit fluid into the wound from the fluid recirculation tube (13), and the bleed T-valve (16) is simultaneously closed.

(In the variant of this apparatus, where there are two inlet pipes (6), which are connected respectively to a fluid supply tube (7) and fluid recirculation tube (13), the first valve (19) is closed and a recirculating system set up by opening the second valve (20) for admitting fluid into the wound from the recirculation tube (13).

15

20

The throughput of the pump (18) is then adjusted to achieve and maintain the desired relatively high rate of irrigant flow across the wound bed which give the appropriate or desired fluid flow rate or velocity of the irrigant and/or wound exudate under the wound dressing to cause flow stress at any appropriate points across the wound bed, e.g. linear velocities of up to 0.03 m/s in a 100 micrometre gap or channel between wound bed and dressing to create a shear stress on the wound bed of the order of 12 - 13 dynes/cm².

The circulating fluid from the wound and the fluid reservoir (12) passes through the ultrafiltration unit (17).

Materials deleterious to wound healing are removed and the cleansed fluid, still containing materials that are beneficial in promoting wound healing, is returned via the recirculation tube (13) to the wound bed.

30

35

The recirculation of fluid may be continued as long as desired.

Switching between supply and recirculation is then reversed, by turning the T- valve (14) to admit fluid from the fluid reservoir to the wound dressing through the fluid supply tube (7) and inlet pipe (6).

(In the variant of this apparatus having two inlet pipes (6), which are connected respectively to a fluid supply tube (7) and fluid recirculation tube (13), the first valve (19) for admitting fluid into the wound from the fluid reservoir (12) is opened and the second valve (20) is shut, and vice versa.)

5

20

25

30

35

The bleed valve (16) is simultaneously opened, so that fresh fluid flushes the recirculating system.

The running of the pump (18) may be continued until the apparatus is flushed, when it and the fluid recirculation is stopped.

If, e.g. the wound is in a highly exuding state, there is a positive change in the balance of fluid in recirculation.

15 It may be necessary to bleed fluid from recirculation, by opening the bleed T-valve (16) to bleed fluid from the recirculation tube (13).

Referring to Figure 2, the apparatus (21) is a variant of that of Figure 1, with identical, and identically numbered, components, except for the means for fluid cleansing, which is in the form of a two-phase system, here a dialysis unit (23).

In this, there is one system through which the circulating fluid from the wound and the fluid reservoir passes and from which deleterious materials are removed by selectively permeable contact with a second system, through which passes a cleansing fluid.

The dialysis unit (23) thus has an internal polymer film, sheet or membrane (24), selectively permeable to materials deleterious to wound healing, which divides it into

- a) a first chamber (25), through which passes a cleansing fluid across one surface of the polymer film, sheet or membrane, and
- b) a second chamber (26), through which passes the circulating fluid from the wound and the fluid reservoir (12), and from which deleterious materials are removed

64

The dialysis unit (23) thus has a dialysate inlet pipe (28) connecting to a dialysate supply tube (29) which passes to a peristaltic pump (38), e.g. preferably a small portable peristaltic pump, acting on the dialysate supply tube (29) with the peripheral rollers on its rotor (not shown) to supply cleansing fluid across the surface of the polymer film, sheet or membrane (28) in the first chamber (25) from a dialysate reservoir (not shown) via a valve (34).

The dialysis unit (23) also has a dialysate outlet pipe (30) connecting to a dialysate outlet tube (31) which passes to waste via a second bleed T-valve (36) into, e.g. a collection bag (not shown).

Operation of this apparatus is similar to that of Figure 1, except for the dialysis unit (27), in that at some point after the irrigation system is primed and steady state recirculation established through the length of the apparatus flow path, the valve (34) and second bleed valve (36) are opened.

The pump (38) is started to nip fluid dialysate tube (29) with the peripheral rollers on its rotor (not shown) to pump cleansing fluid to the first chamber from a dialysate reservoir (not shown) and out to waste via the bleed valve (36) into the collection bag (not shown).

The dialysis unit (23) is a module (or scrubbing cartridge) with a substrate that changes colour to indicate the presence of detrimental factors in the cleansed fluid, and that the scrubbing cartridge is exhausted and should be renewed.

In a variant of the apparatus shown in Figure 2, the dialysis unit has a first chamber (25), but one in which the cleansing fluid is static.

The device for moving fluid through the wound and means for fluid cleansing (17) in Figure 2, a peristaltic pump (18), may optionally act on the fluid supply tube (7) as well as the fluid recirculation tube (13).

5

15

20

25

30

Referring to Figures 3 to 7, each dressing (41) is in the form of a conformable body defined by a microbe-impermeable film backing layer (42) with a uniform thickness of 25 micron, with a wound-facing face (43) which is capable of forming a relatively fluid-tight seal or closure over a wound.

5

10

The backing layer (42) extends in use on a wound over the skin around the wound. On the proximal face of the backing layer (43) on the overlap (44), it bears an adhesive film (45), to attach it to the skin sufficiently to hold the wound dressing in place in a fluid-tight seal around the periphery of the wound-facing face (43) of the wound dressing.

There is one inlet pipe (46) for connection to a fluid supply tube (not shown), which passes through and/or under the wound-facing face (43), and one outlet pipe (47) for connection to a fluid offtake tube (not shown), which passes through and/or under the wound-facing face (43),

15

Referring to Figures 3a and 3b, a suitable form for shallower wounds is shown.

20

This comprises a circular backing layer (42) and a circular upwardly dished first membrane (61) with apertures (62) that is permanently attached to the backing layer (42) by heat-sealing to form a circular pouch (63).

25

The pouch (63) communicates with the inlet pipe (46) through a hole (64), and thus effectively forms an inlet pipe manifold that delivers the circulating fluid directly to the wound when the dressing is in use.

~~

An annular second membrane (65) with openings (66) is permanently attached to the backing layer (42) by heat-sealing to form an annular chamber (67) with the layer (42).

30

The chamber (67) communicates with the outlet pipe (47) through an orifice (68), and thus effectively forms an outlet pipe manifold that collects the fluid directly from the wound when the dressing is in use.

35

Referring to Figures 4a and 4b, a variant of the dressing of Figures 3a and 3b that is a more suitable form for deeper wounds is shown.

This comprises a circular backing layer (42) and a filler (69), in the form of an inverted frustroconical, solid integer, here a resilient elastomeric foam, formed of a thermoplastic, or preferably a cross-linked plastics foam.

It may be permanently attached to the backing layer (43), with an adhesive film (not shown) or by heat-sealing.

A circular upwardly dished sheet (70) lies under and conforms to, but is a separate structure, permanently unattached to, the backing layer (42) and the solid integer (69).

A circular upwardly dished first membrane (71) with apertures (72) is permanently attached to the sheet (70) by heat-sealing to form a circular pouch (73) with the sheet (70).

15

30

10

The pouch (73) communicates with the inlet pipe (46) through a hole (74), and thus effectively forms an inlet pipe manifold that delivers the circulating fluid directly to the wound when the dressing is in use.

20 An annular second membrane (75) with openings (76) is permanently attached to the sheet (70) by heat-sealing to form an annular chamber (77) with the sheet (70).

The chamber (77) communicates with the outlet pipe (77) through an orifice (78), and thus effectively forms an outlet pipe manifold that collects the fluid directly from the wound when the dressing is in use.

Alternatively, where appropriate the dressing may be provided in a form in which the circular upwardly dished sheet (70) functions as the backing layer and the solid filler (69) sits on the sheet (70) as the backing layer, rather than under it. The filler (69) is held in place with an adhesive film or tape, instead of the backing layer (42).

Referring to Figure 5, the dressing is also provided with a wound filler (348) under a circular backing layer (342).

This also comprises a generally toroidal conformable hollow body, defined by a membrane (349) that is filled with a fluid, here a solid particulate, such as plastics crumbs or beads.

- Examples of contents for the body (348) also include gels, such as silicone gels, or preferably cellulosic gels, for example hydrophilic cross-linked cellulosic gels, such as Intrasite ™ cross-linked materials. Examples also include aerosol foams, and set aerosol foams, e.g. CaviCare™ foam.
- The filler (348) is permanently attached to the backing layer (342) via a first boss (351) and a layer of foam (364) formed of a suitable material, e.g. a resilient thermoplastic. Preferred materials include polyurethane foams with small apertures or pores.
- The first boss (351) is heat-sealed to the backing layer (342). The layer (364) may be loose or attached to the boss (351).

An inlet pipe (346) and outlet pipe (347) are mounted centrally in the first boss (351) in the backing layer (342) above the toroidal hollow body (348). The inlet pipe (346) and outlet pipe (347) respectively each extend in a pipe (354) and (355) through a central tunnel (356) in the hollow body (348) to a second boss (357) attached to the toroidal hollow body (348).

20

The pipe (346) extends radially through the second boss (357) to communicate with an inlet manifold (352), formed by a semi-permeable membrane (361) that is permanently attached to the filler (348) by heat-sealing in a reticulated honeycomb pattern, with passageways interconnecting the interiors of the cells of the honeycomb. This has with microapertures (362) that deliver the irrigant fluid directly to the wound bed over an extended area. The pipe (347) collects the fluid flowing radially in from the wound periphery when the dressing is in use.

This form of the dressing is a more suitable layout for deeper wounds

In Figures 6 and 7, the dressing comprises a conformable hollow body that forms an inlet manifold (352).

68

The inlet manifold (352) is defined by an upper, impermeable membrane (349) and a lower semi-permeable membrane (361) that are heat-sealed together around their coterminous periphery.

5 The lower membrane (361), being semi-permeable has a multiplicity of microapertures (363).

The inlet manifold (352) is in the form of a deeply indented circle, generally in the shape of a multiple Maltese cross, so that it in use in a wound the spaces between its arms may close up to make it conformable to the wound bed. It lies at or near the wound bed.

A backing layer (342) forms a relatively fluid-tight seal or closure over the wound by adhesion to the surrounding skin, and traps loose filler, here gauze or elastically resilient foam (353) against the upper surface of the inlet manifold (352), and urges it towards the wound bed.

The inlet pipe (346) passes downwardly (363) to communicate with the interior of the inlet manifold (352).

In Figure 6, the outlet pipe passes through the backing layer (342) to just below its wound-facing face (343).

25

10

A variant of the dressing of Figure 6 is shown in Figure 7. The outlet pipe (347) is mounted to open at the lowest point of the manifold (352) into a piece of foam (354).

30

In both variants, the microapertures (363) distribute fluid radially towards the wound periphery when the dressing is in use. The fluid passes through a gap (355) between the inlet manifold (352) and the wound surface and flows through the filler (353) to be collected by the outlet pipe (347).

Referring to Figure 8, another form for deeper wounds is shown. This comprises a circular, or more usually square or rectangular backing layer (342) and a chamber (363) in the form of a deeply indented disc much like a multiple Maltese cross or a stylised rose.

5

This is defined by an upper impervious membrane (361) and a lower porous film (362) with apertures (364) that deliver the irrigant fluid directly to the wound bed over an extended area, and thus effectively forms an inlet manifold. Three configurations of the chamber (363) are shown in Figure 27b, all of which are able to conform well to the wound bed by the arms closing in and possibly overlapping in insertion into the wound.

The space above the chamber (363) is filled with a wound filler (348) under the backing layer (342).

15

10

The filler comprises an oblately spheroidal conformable hollow body, defined by a membrane (349) that is filled with a fluid, here air or nitrogen, that urges it to the wound shape.

20

A moulded hat-shaped boss (351) is mounted centrally on the upper impervious membrane (361) of the chamber (363). It has three internal channels, conduits or passages through it (not shown), each with entry and exit apertures. The filler (348) is attached to the membrane (361) of the chamber (363) by adhesive, heat welding or a mechanical fixator, such as a cooperating pin and socket.

25

30

An inflation inlet pipe (350), inlet pipe (346) and outlet pipe (347) pass under the edge of the proximal face of the backing layer (342) of the dressing, and extend radially immediately under the filler (348) and over the membrane (361) of the chamber (363) to each mate with an entry aperture in the boss (351).

An exit to the internal channel, conduit or passage through it that receives the inflation inlet pipe (350) communicates with the interior of the hollow filler (348), to permit inflation.

30

35

An exit to the internal channel, conduit or passage that receives the inlet pipe (346) communicates with the interior of the chamber (363) to deliver the irrigant fluid via the chamber (363) to the wound bed over an extended area.

- Similarly, an exit to the internal channel, conduit or passage that receives the outlet pipe (347) communicates with the space above the chamber (363) and under the wound filler (348), and collects flow of irrigant and/or wound exudate radially from the wound periphery.
- Referring to Figure 9, the apparatus (1) for aspirating, irrigating and/or cleansing wounds is a variant of the apparatus (1) of Figure 1.
- It has bypass (711) around the pump (17), as a protection of the pump against any blockage in the system.
 - It is activated automatically by appropriate means, e.g. it is normally blocked by a bursting disc (not shown), or a pressure-activated motorised valve.
- 20 An alternative to the by-pass (711) is a pressure sensor in the system that will detect excessive load or pressure, and shut down the pump.
- Referring to Figure 10, the apparatus (1) for aspirating, irrigating and/or cleansing wounds is a variant of the apparatus (1) of Figure 2.
 - The latter is a two-phase system with a dialysis unit (21), but is one in which dialytic fluid passes only once across the surface of the dialytic membrane (28) in the first chamber (25) from a dialysate reservoir (not shown) to waste via a second bleed T-valve (36) into, e.g. a collection bag (not shown).
 - This variant has a dialysate recirculation tube (811) running between a first T-valve (816) on the inlet side of the dialysate pump (23) and a second T-valve (817) to permit the pump (23) to recirculate the dialysate once the circuit is primed in multiple passes through the dialysis unit (21).

The operation of the system will be apparent to the skilled person.

WO 2005/105176

The use of the apparatus of the present invention will now be described by way of example only in the following Examples:

Example 1. The combination of the removal by dialysis of materials deleterious to wound healing (H₂O₂) by an enzyme (catalase) retained in a static second phase and stress.

An apparatus of the present invention was constructed essentially as in the variant of the apparatus of Figure 2 described above, i.e. one in which the means for fluid cleansing is a two-phase system dialysis unit.

10

In such an apparatus, an irrigant and/or wound exudate first phase from the wound recirculates through a first circuit and passes in contact, across a selectively permeable dialysis membrane, with a static second fluid (dialysate) phase.

15

20

25

Hydrogen peroxide is produced in conditions of oxidative stress following reduced blood flow and or the inflammatory response to bacterial contamination of wounds. It may be removed by the appropriate antagonists and/or degraders, which include enzymic or other inhibitors, such as peroxide degraders, e.g. catalase.

The first circuit comprised a surrogate wound chamber (Minucells perfusion chamber) in which normal diploid human fibroblasts were cultured on 13 mm diameter (Thermanox polymer) cover slips retained in a two part support (Minucells Minusheets). Tissues present in the healing wound that must survive and proliferate were represented by the cells within the chamber.

30

After an overnight serum starvation, nutrient medium (DMEM with 10% FCS with 1% Buffer All) to simulate wound exudate was pumped from a reservoir into the lower aspect of the chamber where it bathed the fibroblasts and was removed from the upper aspect of the chamber and returned to the reservoir.

The first circuit also

35

a) includes, upstream of the wound chamber, a static second phase dialysis unit, comprising a length of dialysis tubing (Pierce Snake skin 68100 CG 49358B, 10KD cut off) placed within the first circuit reservoir.

WO 2005/105176

5

10

25

In the dialysis unit a static second phase second cleansing circuit containing nutrient media with between 5,000 and 50,000 units (μ moles H_2O_2 degraded per min at pH7, 25°C) per ml of catalase (in a circuit with a reservoir and total volume of between 5.0 ml and 15 ml), and

b) is operated at a flow rate of between 14μl min⁻¹ and 1.4 ml min⁻¹.

The pump was a peristaltic pump acting on silicone (or equivalent) elastic tubing. The internal diameter of the tubing was 1.0 mm. A total volume for the first circuit including the chamber and the reservoir at a number of values between 25 and 79 ml was used. The flow rates used were at a number of values between 14µ ml min⁻¹ and 1.4 ml min⁻¹.

An experiment was conducted that simulated conditions not uncommon for non-healing wounds whereby the nutrient medium containing a material deleterious to wound healing, namely hydrogen peroxide, was circulated over the cells.

A flow stress stimulation, comprising of an initial fast flow rate of 1.4ml min⁻¹ for 6 hours was then followed by a slow flow rate of 14µl min⁻¹ for 42 hours, during this procedure the fibroblasts survive and proliferate.

A control experiment is also conducted where the flow rates remain constant at either 14μ l min⁻¹ or at 1.4 ml min⁻¹ and a control that has flow stress, but cleansing was omitted. Additional controls used the combination chronic wound element (H_2O_2) and flow stress but no catalase.

Results and Conclusions

- A. The following results were obtained for a first phase circuit comprising a wound chamber as above containing nutrient media (79ml) with H₂O₂ (10μM) and flow stress (a flow rate of 14μ l min⁻¹ for 6 hours and 1.4 ml min⁻¹ for 42 hours) in contact with a static second phase (15 ml) containing catalase (5,748 units ml⁻¹), where the wound chamber and media were held at 37°C for a total of 48 hours.
 - B. Additional control systems comprising a first phase circuit comprising a wound chamber run for a total of 48 hours at 37°C, including:

- a) nutrient media elements pumped at flow rates of 14μ l min⁻¹ or 1.4 ml min⁻¹
- b) flow stress only , (using different flow rates of ~ 14 μ l min⁻¹ for 6 hours and 1.4 ml min⁻¹ for 42 hours).
- c) flow stress plus media (79ml) containing H₂O₂ (10μM)

All described control systems omitted contact with a second static phase (15ml) containing catalase,

| Conditions | Mean level of cell activity*(n=2) after a |
|--------------------------------------------------|-------------------------------------------|
| | total of 48 hours |
| | incubation. |
| Nutrient media only at 14μl min ⁻¹ | 0.07 |

5

*Cell activity measured with a WST (Tetrazolium based mitochondrial dehdrogenase activity assay).

In the controls where either

WO 2005/105176 PCT/GB2005/001588

74

- a) the passage of the nutrient flow across the cleansing membrane dialysis unit or
- b) the flow stress (initial fast flow rate of 1.4ml min⁻¹ for 6 hours was then followed by a slow flow rate of 14µl min⁻¹ for 42 hours) was omitted
- 5 the growth and survival of the fibroblasts was not enhanced.

If in addition the concentration of H_2O_2 lies between 5 and 20 mM, the survival and growth of the fibroblasts is inhibited.

- 10 However, when the nutrient medium flow in the first circuit is
 - a) passed over the membrane dialysis unit in which a second cleansing circuit containing catalase (at the concentrations and flow rates noted above) is present, and
- b) flow stress (initial fast flow rate of 1.4ml min⁻¹ for 6 hours was then followed by a slow flow rate of 14µl min⁻¹ for 42 hours) was applied the fibroblasts survive and proliferate to a greater extent than in the control circuits.
- The combination of the wound cleansing dialysis unit that removes and degrades H₂O₂ and flow stress comprising of a flow rate of 14µ l min⁻¹ for 6 hours and 1.4 ml min⁻¹ for 42 hours enhances the cell response necessary for wound healing.
- 25 Example 2: The combination of the removal by dialysis of materials deleterious to wound healing (H₂O₂) by an enzyme (catalase) retained in a moving second phase in combination with flow stress.
 - An apparatus of the present invention is constructed essentially as in Figure 2, i.e. one in which the means for fluid cleansing is a two-phase system dialysis unit. In such an apparatus, an irrigant and/or wound exudate first phase from the wound recirculates through a first circuit and passes in through the dialysis unit in contact across a selectively permeable dialysis membrane with a second fluid (dialysate) phase. The dialysis unit is operated with the two phases flowing counter-current to each other.

WO 2005/105176 PCT/GB2005/001588

75

Hydrogen peroxide is produced in conditions of oxidative stress following reduced blood flow and or the inflammatory response to bacterial contamination of wounds.

It may be removed by the appropriate antagonists and/or degraders, which include enzymatic or other inhibitors, such as peroxide degraders, e.g. catalase.

The first circuit comprised a surrogate wound chamber (Minucells perfusion chamber) in which normal diploid human fibroblasts are cultured on 13 mm diameter (Thermanox polymer) cover slips retained in a two-part support (Minucells Minusheets). Tissues present in the healing wound that must survive and proliferate are represented by the cells within the chamber. After overnight serum starvation nutrient medium (DMEM with 10% FCS with 1% Buffer All) to simulate wound exudate is pumped from a reservoir into the lower aspect of the chamber where it bathed the fibroblasts and is removed from the upper aspect of the chamber and returned to the reservoir.

The first circuit also

- a) comprised upstream of the wound chamber, a luer-fitting hollow fibre tangential membrane dialysis unit (Spectrum® MicroKros® X14S-100-04N, 8 cm² surface area, 400KD Mol. Wt. cut off,) through which a second cleansing circuit containing nutrient media with between 5,000 and 50,000 units (μ moles H₂O₂ degraded per min at pH7, 25°C) per ml of catalase (in a circuit with a reservoir and total volume of between 5.0 ml and 20 ml) at a flow rate of between 14μl min⁻¹ and 1.4ml min⁻¹ could be passed in a counter current direction, and
 - b) was operated with a flow stress consisting of differential flow rates pumped at 14μ l min⁻¹ for 6 hours and 1.4 ml min⁻¹ for 42 hours

The pumps for the two circuits are peristaltic pumps acting on silicone tubing or equivalent. The internal diameter of the tubing is 1.0 mm. A total volume for the first circuit including the chamber and the reservoir at a number of values between 25 and 75 ml is used.

30

10

WO 2005/105176 PCT/GB2005/001588

76

Experiments are conducted that simulated conditions not uncommon for non-healing wounds whereby the nutrient medium containing a material deleterious to wound healing, namely hydrogen peroxide, is circulated over the cells.

5

First and second control apparatus are also constructed essentially as in Figure 2, but where either

- a) the cleansing membrane dialysis unit is omitted, so that the nutrient flow passes directly from the reservoir, or
- 10 c) flow stress consisting of a flow rate 14μ l min⁻¹ for 6 hours and 1.4 ml min⁻¹ for 42 hours is omitted

In controls where either

- a) the passage of the nutrient flow through the cleansing membrane dialysis
 unit or
 - b) flow stress consisting of a flow rate 14μ l min⁻¹ for 6 hours and 1.4 ml min⁻¹ for 42 hours is omitted, the growth and survival of the fibroblasts is not enhanced.
- 20 If in addition, the concentration of H₂O₂ lies between 5 and 20 mM, fibroblast activity and proliferation is inhibited

However, when the nutrient medium flow in the first circuit is connected into the ends of the membrane dialysis unit through which a second cleansing circuit containing catalase (at the concentrations and flow rates noted above) is passing in a counter current direction, and flow stress consisting of differential flow rates pumped at 14µ l min⁻¹ for 6 hours and 1.4 ml min⁻¹ for 42 hours, the fibroblasts survive and proliferate to a greater extent during a 48 hour period than the control circuits.

Claims

10

15

20

- 1. An apparatus for irrigating, flow stressing and/or cleansing wounds, characterised in that it comprises
- 5 a) a fluid flow path, comprising
 - i) a conformable wound dressing, having a backing layer which is capable of forming a relatively fluid-tight seal or closure over a wound and
 - at least one inlet pipe for connection to a fluid supply tube, which passes through and/or under the wound-facing face, and and at least one outlet pipe for connection to a fluid offtake tube,

which passes through and/or under the wound-facing face, the point at which the or each inlet pipe and the or each outlet pipe passes, through, and/or under the wound facing face face for in the

passes through and/or under the wound-facing face forming a relatively fluid-tight seal or closure over the wound,

at least one inlet pipe being connected to a fluid recirculation tube, and at least one outlet pipe being connected to a fluid offtake tube: and

- ii) a means for fluid cleansing having at least one inlet port connected to a fluid offtake tube and at least one outlet port connected to a fluid recirculation tube;
- b) a fluid reservoir connected by a fluid supply tube to an integer of the flow path (optionally or as necessary via means for flow switching between supply and recirculation):
- c) a device for moving fluid through the wound dressing and means for fluid cleansing, and optionally or as necessary the fluid supply tube; and
 - d) optionally means for bleeding the flowpath, characterised in that it comprises
- e) means for applying flow stress to the wound bed; and such that fluid may be supplied to fill the flowpath from the fluid reservoir via the fluid supply tube (optionally or as necessary via the means for flow switching) and recirculated by the device through the flow path.
- 35 2. An apparatus according to claim 1, characterised in that the means for applying flow stress to the wound bed comprise means for applying, controlling and/or varying irrigant and/or wound exudate flow under the wound dressing.

3. An apparatus according to claim 1 comprising an irrigant inlet manifold in the dressing which contacts or lies very close to the wound bed, with apertures or pores by the wound bed that are distributed over an extended area, characterised in that the means for applying flow stress to the wound bed comprises a device for moving fluid through the wound, the throughput of which causes a relatively high pressure drop between the interior of the manifold and the wound bed.

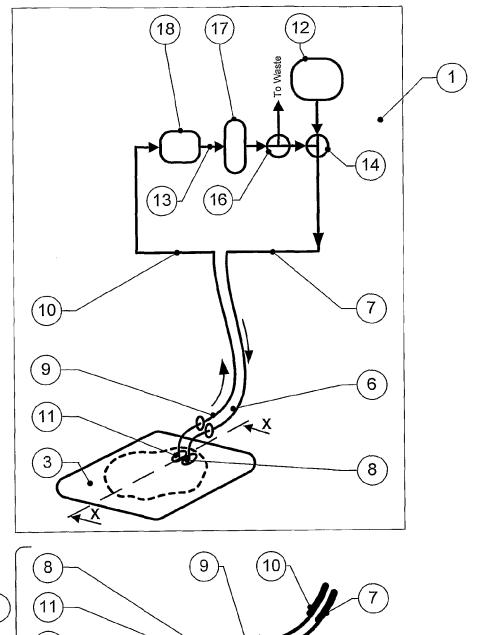

5

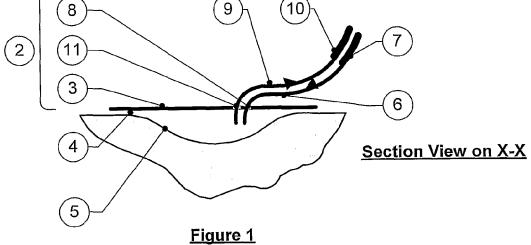

15

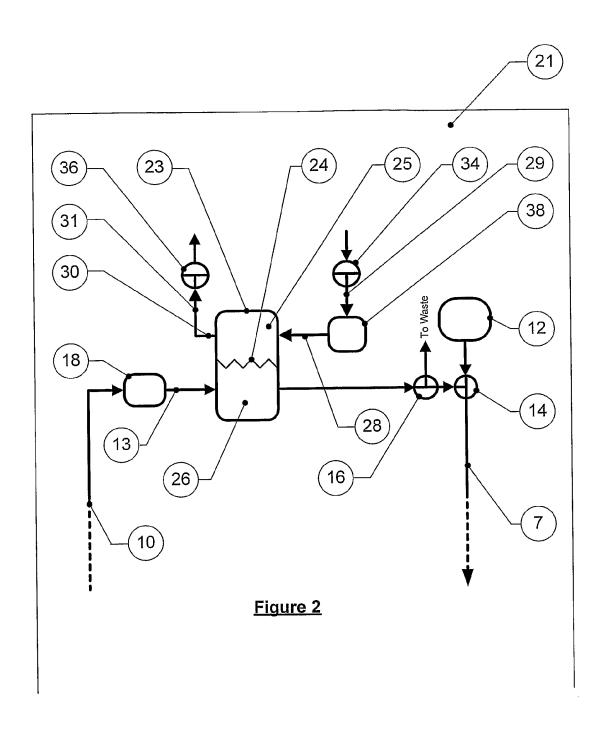

30

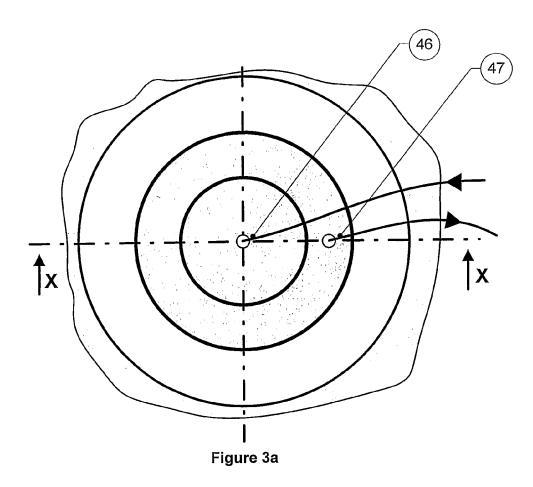

- An apparatus according to claim 1, characterised in that the means for
 applying flow stress to the wound bed comprises projections on the wound-facing face of the dressing, that are capable of directing flow.
 - 5. An apparatus according to claim 1, characterised in that it comprises a means for fluid cleansing that is a single-phase system, in which the circulating fluid from the wound passes through the means for fluid cleansing and materials deleterious to wound healing are removed, without the circulating fluid coming into direct or indirect contact with another fluid in the means for fluid cleansing.
- 20 6. An apparatus according to claim 1, characterised in that it comprises a means for fluid cleansing that is a two-phase system, in which the circulating fluid from the wound passes through the means for fluid cleansing and materials deleterious to wound healing are removed, by the circulating fluid coming into direct or indirect contact with another fluid in the means for fluid cleansing.
 - 7. An apparatus according to claim 3, characterised in that in the means for fluid cleansing, the circulating fluid from the wound and the other fluid in the means for fluid cleansing are separated by an integer which is selectively permeable to materials deleterious to wound healing.
 - 8. An apparatus according to claim 3, characterised in that in the means for fluid cleansing, the circulating fluid from the wound and the other fluid in the means for fluid cleansing are separated by an integer which is not selectively permeable to materials deleterious to wound healing, and the other fluid comprises and/or is in contact with a material that removes materials deleterious to wound healing.

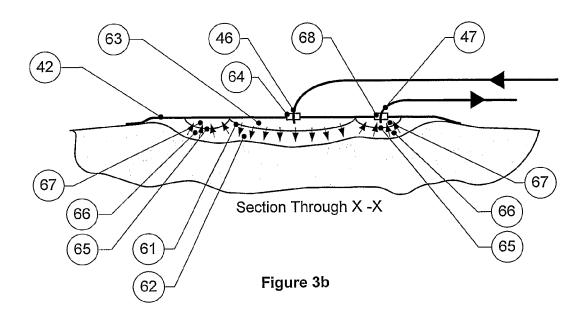

- 9. A conformable wound dressing for use in an apparatus according to claim 1 that comprises
 - a backing layer with a wound-facing face which is capable of forming a relatively fluid-tight seal or closure over a wound and has
- at least one inlet pipe for connection to a fluid supply tube, which passes through and/or under the wound-facing face, and
 - at least one outlet pipe for connection to a fluid offtake tube, which passes through and/or under the wound-facing face,
- the point at which the or each inlet pipe and the or each outlet pipe passes through and/or under the wound-facing face forming a relatively fluid-tight seal or closure over the wound,
 - characterised in that it comprises means for applying flow stress to the wound bed.
- 15 10. A method of treating wounds to promote wound healing using the apparatus according to claim 1.

| Box II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet) | |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons: | |
| 1. X Claims Nos.: 10 because they relate to subject matter not required to be searched by this Authority, namely: | |
| Rule 39.1(iv) PCT - Method for treatment of the human or animal body by therapy | |
| 2. Ciaims Nos.: because they relate to parts of the international Application that do not comply with the prescribed requirements to such an extent that no meaningful international Search can be carried out, specifically: | |
| Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a). | |
| Box III Observations where unity of invention is lacking (Continuation of item 3 of first sheet) | |
| This International Searching Authority found multiple inventions in this international application, as follows: | |
| | |
| | |
| As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims. | |
| 2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee. | |
| 3. As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Ncs.: | |
| 4. No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.: | |
| Remark on Protest The additional search fees were accompanied by the applicant's protest. No protest accompanied the payment of additional search fees. | |
